Eighty tons is being raised daily, which can be increased to 100 tons without overworking or injuring the mine. The ore is sent down from the tunnel to the ore house on an incline in summer, and in stone boats in winter, the latter working much the best, and carrying down twice the quantity of ore in half the time. The mine is under the management of Captain Goldsworthy, who has had eighteen years experience in silver lead mines in England, and is fully capable of managing all the underground workings of this extensive property.

The furnaces, which are situated at the mouth of the cañon, are three in number, one hot and two cold blast furnaces, and are capable of smelting 75 tons of ore daily, which makes 25 tons of bullion, valued at \$340 per ton, \$55 of which is gold.

The assay value of ore is:
70 oz. silver, 50 per cent. lead, $\frac{3}{4}$ oz. gold.
100 " " " " " "

The hot blast furnace, the only one in the Territory, works very successfully, saving greatly in charcoal, and losing no lead. The furnaces are run by water power, the company

having the full water privilege of the Cottonwood Creek.

The furnaces are under the able management of L. M. Wessels.

This company is being very successfully worked and pays largely to its shareholders, and from present indications will continue for years to come.

Dividends 30 per cent. per annum, or 2½ per cent. per month are paid, £69,000 having already been paid in dividends.

The whole is under the superintendence of Mr. N. M. Maxwell.

THE WINSON UTAH SILVER MINES,

Of Little Cottonwood District, comprising the Last Chance, Hiawatha, Montezuma, and Savage lodes were consolidated September 12, 1872, and are owned and controlled by parties in Utah, Michigan and New York. Since this property was consolidated the owners have marketed about 500 tons of ore at an average selling value of \$60 per ton. This property is now being vigorously worked on ore. The veins in the bottom of the Last Chance and Savage lodes are yielding fine ore assaying from \$160 to \$307 per ton, and carry from 34 to 60 per cent. of lead. The present depth of the Last Chanceshaft is 366 feet; depth of the Montezuma shaft 375 feet; length of tunnels on the property 550 feet; depth of Savage and Hiawatha shaft 350 feet. The company have erected a fine hoarding-house, ore house and other buildings necessary to economically handle their property during winter, and have connected the various outlets to their mines by cross tracks to the main tramway, and are prepared to mine and ship ore to good advantage during the present winter. The amount of ore now in sight in the Montezuma mine carries a face three feet wide the entire length of the

shaft. The Last Chance vein is eighteen inches thick. The winzes in the Savage and the Savage Discovery shaft have a fine body of ore averaging from 7 to 31 inches in thickness. The Hiawatha incline has a good show of mineral its entire length. This property will compare favorably with any property on Emma Hill either for quantity or quality of its ore at the same depth and outlay for work done. The

whole is under the superintendence of Mr. J. C. Winslow.

THE MILLER MINE.

This mine is located near the head of American Fork Cañon, on what is known as the Middle Mountain. The lode occurs at the point of contact of the limestone and quartzite. The ore is mostly carbonate of lead, carrying silver and gold, and is a very free smelting ore. The mine at the present time is being prospectively worked with a view to next season's work. This mine is owned by the Miller Mining and Smelting company of New York. Francis Skiddy, president; Gen. Lloyd Aspinwall, chairman of Executive committee; E. Wilkes, general manager.

The Miller ore is smelted at the Siltana Furnace, two and one-half miles distant, situated in American Fork Cañon.

These works consist of three shaft furnaces of a capacity of seventy tons of ore per day.

The works are complete in every respect. The blowing arrangements consist of a No. 10 Striteant Blower driven by a 25-horse power. The charcoal is burnt on the ground; the company have fifteen kilns for the purpose; these are connected with the furnaces by a tram road delivering the coal immediately at the furnace mouth.

To this point it is intended to run the American Fork railroad. The grading is now completed.

THE MONO MINE,

Located on Dry Cañon, Ophir District, is owned by Messrs. Gibborn, Embody & Heaton. The extraordinary richness of some of its ores has already been referred to. A description of the mine may be of some interest. The incline shaft is down 308 feet. Starting from a point 40 feet from the bottom of incline, there are five drifts run on the left and three on the right of the main shaft. The vein of ore which has the appearance of a true fissure vein, averages about two feet; about three inches of it are said to be horn-silver and black sulphurets.

The vein runs nearly east and west and pitches to the north at an angle of twenty-eight degrees. There is a fine large ore-house, also a dwelling house, office and blacksmith-shop. The owners confidently believe they have as good a mining property as any in the Territory.

THE PRINCE OF WALES AND ANTELOPE MINE, Situated in Silver Fork, Big Cottonwood Cañon, is remarkable for its well-defined vein of ore which can be traced on the surface for a distance of five hundred feet. The average assay value exceeds \$150 per ton. The mine has been worked more than two years, and a large amount of labor performed on it, including 863 feet of tunneling, shafting and drifting, the course of the vein being followed the whole distance.

THE TIGER GROUP OF MINES,

Situated on Lion Hill, Ophir District. This group includes the Tiger, Silver Chief, Zella and Rockwell. These mines were discovered in the fall of 1870. They are all being vigorously worked. The lowest workings are to the depth of 250 feet. The extent of tunneling and shafting done in these mines exceeds any other in the Territory, it aggregating 2,580 feet. Between three and four thousand tons of ore have been taken out of the mines, the average value being about \$125 per ton. Some specimens have assayed as high as \$1,000 per ton.

The names of the following mines have been furnished since the description of the districts was in type:

AMERICAN FORK DISTRICT.

The Waterloo lode, discovered the same day as the Miller. It is in the same cañon, and directly opposite the Miller. A shaft sixty feet deep has been sunk, disclosing a vein of

BED-LOUNGE OPEN.

BED-LOUNGE SHUT.

high grade ore. The Walker lode has also a shaft ninety feet deep, and has a quantity of fine ore on the dump. Other mines of equal merit may be mentioned, among them are the Chelsea, the Champion and Emeline, all promising and well defined lodes.

LYON HILL, OPHIR DISTRICT.

The Monarch and the Virginia series, em-

bracing the Virginia, Lizzie, M. C. Raymond, State of Maine, Dudley Gray, Julia, Bay State and others. The character of ores is strictly milling. The silver is in the form of chlorides and sulphides—the former predominating. Assays of the ore run from \$40 to as high as \$1,000 to the ton.

CAMP FLOYD DISTRICT.

The Camp Douglas Consolidated has a shaft forty-seven feet in depth and two open cuts. The Star of the West, owned and worked by a New York company, is developed by several open cuts and shafts. The Stafford is a well defined vein. It is being worked by open cuts and a tunnel sixty feet in length. The Carrie Steele adjoins this mine and is promising well. The Silver Circle, Wandering Boy, Legal Tender, Comstock, Silver Star, America, Excelsior, and Lone Star are all considerably developed and promise well. The General Morrow has a shaft fifty-five feet deep and is very promising. The Antelope has a shaft seven by seven and twelve feet deep, also an open cut six feet wide and ten feet deep. The ore is of good quality from all these mines and assays high.

PROSPECTING WITH DRILLS.—They are beginning to prospect for ore with the Diamond Drill at Washoe, on the same plan as which artesian wells are bored. The Gold Hill News says that General Williams and Mr. Shultz, of the Bullion mine, have already sunk a miniature shaft 400 feet deep with a two-inch diamond drill. They are working on some level ground, half a mile distant from the Ophir works. If this plan meets with success, it will doubtless be tried in other localities. As the plan was tried of drilling in this manner laterally to find the size and character of the great ore-body in one of the Washoe mines, some time since, and answered well, we see no reason why the method spoken of will not accomplish like results.

Pratt's Improved Bed-Lounge.

Bed-lounges are always convenient in small houses, either in the country or city, and, in fact, sometimes are found quite handy, even in large buildings. In case of an extra visitor, some of the family can give up their rooms and sleep on the lounge, or children can be put there in the nurses' room. The two cuts shown on this page give an idea of an improvement in this direction, which is now being introduced on this Coast, and which has been in use extensively in the East, especially in large cities where rents are high. The lounge is upholstered the same as ordinary lounges, and, when folded, there is no perceptible difference. The circular part of the head is made hollow, to form a receptacle for the bed-clothes; but when thrown upon the head-piece has a suitable inclination for comfortable sleeping. There are springs throughout the bed, covered with heavy canvas, and the bed is wide enough for two persons to sleep comfortably.

When used as a lounge, the legs can be folded in, out of sight, and it then presents the appearance of an ordinary lounge. Settees or sofas are constructed on the same principle as the lounge, and made in such a manner that the casual observer would not notice that they served a double purpose. These articles of household furniture, combining as they do, both the useful and ornamental, are durable and well made. Wiester & Co., No. 17 New Montgomery street, have the patent-right of the Pacific Coast for sale, and parties desiring further information can call on them and get particulars.

Winter in the Mines.

The Deer Lodge Independent has the following very excellent suggestions which might well be adopted in other mining localities:

The nature of our climate prevents successful surface mining in the winter season. Usually all surface mining is suspended before Christmas and is not resumed until some time in the month of April following. This gives miners a convenient time for rest and recreation. Some go East to visit the "old folks at home," others remain and employ part of their time in preparing for the summer campaign, by the construction of sluices, flumes, hydraulic telegraphs, sawing blocks for sluice and flume rifles, cutting ditches, digging drains, prospecting, etc. In fact none need be idle or unprofitably employed. If a number of miners have leisure during the winter months and do not wish to engage in manual labor of the kind mentioned, the season of rest affords a splendid opportunity for intellectual culture and social intercourse, and those who supply themselves with books, papers, periodicals, etc., may find a winter spent in a mountain mining town one of the most profitable and pleasant of any in the whole course of a lifetime. There is a pleasure derived from a self-consciousness of having made good use of the passing moments, in an earnest effort of self improvement, and every step taken in this direction is an acquisition of wealth, more enduring than the glittering nuggets we accumulate during the mining season. In order therefore to extend such advantages to as wide a circle as possible we would suggest the establishment of local libraries in the mining towns, which may be done at small expense. Books weighing four pounds may be ordered through the Post-office at a cost of only 32 cents postage. There is therefore no excuse for any individual to be wanting good books or late publications, as the U. S. mails deliver them at rates as low as merchants pay on groceries received by the slow mode of "narrow gauge" or teams. Our deep diggings, such as the drifting ground of Bear, Lincoln, Gold Cañon, French, Pioneer, Upper Ophir, Maginnis and other places afford constant employment, but the great majority of placers are worked from the surface, and many men have leisure to engage in reading, study, etc., which would in the end prove to them a saving of money, and add to the individual and general happiness and contentment of all.

COAL.—An English paper, speaking of the large amount of coal imported from the United States into the United Kingdom, thinks it probable that eventually a system of iron steam colliers of large tonnage will carry United States coal to all parts of the world. Some vessels now loading for the export trade have a capacity of 4,000 tons.

WHERE THE IRON GOES.—If the total length of railroads in all countries is 146,243 miles, as has been computed, it is not surprising that their maintenance, together with new construction, takes more than half the iron production of the world. Europe has 48 per cent. and America 47 per cent. of the whole.

A NOVEL BUTTON.—It is said that a Massachusetts woman has just patented a self-fastening button, which needs no button hole, holds fast, and yet unbuttons at a touch.

USEFUL INFORMATION.

CURIOSITIES OF THE BOSTON RUINS.—Although it is more than two months since the great fire, the rains and snows of winter have not succeeded in entirely quenching it. In many parts of the burnt district dense columns of smoke are still ascending, and bright flames dart out from beneath piles of brick and granite. The influence of heat upon various kinds of merchandise found among the ruins has afforded examples of metamorphosis interesting and curious in a high degree. Huge piles of leather in some cases were precipitated into cellars, and so covered with debris as to undergo a kind of dry distillation, or fusing out of contact with air. The resultant mass resembles a dry gum, with a clean vitreous fracture, upon the surfaces of which are seen the lines between the hides, like thin strata in a mass of silt. We have a lump of coke, produced from clover seed, which closely resembles cannel coal. It came from a mass of two thousand bushels which tumbled into a cellar, and was subjected to dry distillation under the bricks and mortar. Many other substances have undergone curious changes, and we may allude to some of them at a future time.—*Boston Journal of Chemistry.*

DURABILITY OF WOOD.—We expect wooden buildings to decay, and if they endure for a century or two they are regarded as venerable specimens of antiquity. The First Baptist meeting-house in Providence, R. I., a fine architectural model is said to be as sound, even to the top of its lofty spire, as when first built, though nearly a century old. But this is a young infant compared with some European churches. The trusses of the old part of the roof of the Basilica of St. Peter's at Rome, were framed in 816, but when carefully examined in 1814 were found to be perfectly sound and good. They were made of fir, and have lasted over a thousand years. The domes of the church of St. Marks, at Venice, were built nearly eight hundred and fifty years ago, and the outside timbers are yet good. Brick and stone could hardly last better than such wood-work.

Timber cased in plaster and in iron, however, has developed a very dangerous kind of dry rot.

HOW TO CLEAN PAINT.—A chemical journal gives the following advice: Use but little water at a time; keep it warm and clean by changing often. A flannel cloth is better than cotton. Be careful of soap. Put but a little soap or skin-milk in the water; add soap to the cloth when needed. A sharp piece of soft wood is indispensable for the corners; the point will become like a paint brush. A saucer of sifted ashes, used where paint is badly smoked or fly-specked are thick, is better than soap; wipe last with clean wet towel, and don't spill a drop of water. Never put soap on glass unless it can be well rinsed, which can never be the case with windows; wash off dirt in clean warm water and dry; then, with a paste of whiting and water, and with a little cloth, place a little in the centre of each pane. With another cloth rinse over the glass; next rub off with a dry cloth till the window shines like crystal.

MANUFACTURE OF MAD STONES.—A Virginia paper says there is a man in that State who is engaged in the manufacture of mad stones for the cure of hydrophobia. The original mad-stones were brought from France and Italy, and have the appearance and the weight of the more porous kind of bone. The domestic manufacturer gets the bone itself, and saturates it with some chemical or other, and sells small bits of it at \$5 each. Besides its virtue as a relief for hydrophobia, the bone is said to cure tetanus. "The cases of lock jaw," says the Virginia Editor, "are too few to make this discovery important. Can't some one invent a cure for *limber jaws*? They cost the State a great deal."

TO COPY MANUSCRIPTS.—Press copies of old letters or manuscript can be taken by pressing the pages on the damp paper in the usual way, and then applying the vapor of ammonia. Although no result may appear to follow the first operation, we are assured that after the second, the letters will appear distinctly on the dampened blotting paper. Another method consists in dampening the manuscript with a solution of sugar, honey, or mucilaginous matter, and then applying applying the dampened paper as heretofore. In this case the sugar is applied to the paper instead of being mixed previously in the ink, as is done in one form or other with ordinary copying ink.

HARNES DRESSING.—Long continued observations show that harness and other leather, exposed to the action of ammonia continually given off in stables, become weak and rotten sooner than other leather. Even when care is taken to protect it with grease, this takes place. Professor Artns recommends the addition of a small quantity of glycerine to the oil or fat employed in greasing such kind of leather, ascertaining that it keeps it always pliable and soft.

CARBON-PAPER.—The "carbon-paper" used for tracing and in manifold writing, is made by filling the pores of soft unsized paper with lamp-black. Oil—castor-oil or lard—is mixed with the black, and as much is rubbed into the paper as it will hold, and all that is superfluous is wiped off with soft cloths.

PALM WINE.—The sap of the palm tree runs quite freely from an incision through the bark. It is put into skin bottles, or rather bags, by African wine-makers in which it undergoes a slight degree of fermentation, and is soon ready for use. Every time the mouth of the bag is untied for taking a drink, it foams and sputters very much like spruce beer. Although all the gas may escape, shortly after being tied up again there is another volume ready to fizzle as before.

Christian travelers are quite as fond of palm wine as natives. Without being much of a stimulant, it has a relish that meets the demands of the system in a hot climate far better than any other drink. Of course it is in universal demand, and costs nothing but the labor of gathering the sap from the nearest tree, without asking leave.—*Southern Homestead.*

REMOVING PAINT FROM WINDOWS.—Inexperienced painters, when painting window casings and sashes, frequently spatter paint in minute dots over the surface of many of the panes, where it is left until it becomes dry and hard. Neat workmen always have a clean cloth or sponge, which is dipped in a little spirits of turpentine, and the paint is rubbed off before it is dried. After the paint has become dry and hard, strong soap-suds will not remove it without a vast deal of hard rubbing. The most economical way to remove dry paint from the panes is to make a small swab, having a handle some eight inches long, dip it in a little diluted oxalic acid, and rub off the paint with the swab.

THE BABYLONIAN WILLOWS.—The *Journal of Horticulture* says: "The willow which grew 'by the waters of Babylon,' whereon the mournful children of Judah hung up their harps, was not, as Linnæus and others have supposed, the *Salix Babylonica*. It is now thought to be a kind of poplar. The ordinary weeping willow has been brought from China and Japan."

In this connection we may remark that the *Gardener's Monthly* points out the absurdity of the supposed origin of Pope's Willow at Twickenham, which was said to have come from an old hamper basket which was found along the Thames, and had come from the Mediterranean. Any one ought to know that no basket ever was made of the weeping willow.

TRELLIS COLUMNS.—Telegraph posts and columns are manufactured in Manchester of spirals of iron-ribbands, in fact, supported on a cast-iron base, and surmounted with a capital of the same material. A slender rod forms the axis of the column, or, as it really is, a trellis-work tube. Compared with cast-iron columns, these structures are little more than one-third either in weight or cost, while in appearance the gain is decidedly great. For conservatories or other horticultural purposes the trellis column is very suitable. Such a pillar, eleven feet high and eight inches in diameter, is guaranteed to support a vertical pressure of one ton.

AMERICAN IMPLEMENTS IN ENGLAND.—It is an interesting fact that Philadelphia is now shipping saws to England. Shoemakertown, on the outskirts of Montgomery county, and a few miles from Philadelphia, also sends hay-forks, dung forks, and pitch-forks to Sheffield, England, the very centre of her iron and steel manufactory, while Ames shovels from Massachusetts supply England and the rest of the world. American ingenuity has so improved the quality and cheapened the cost of these implements that the tide is turned—we send to England instead of getting them from there.

KILLING KNOTS.—Glue size and red lead Gum shellac dissolved in alcohol, and mixed with red lead. Gutta percha dissolved in ether. But through all or any of these will the pitch of the knot exude if exposed to the sun. Perhaps the very best method is, to size the knot with oil size, and then lay a leaf of gold or silver on it. In a very choice piece of work, a hot iron may be held over the knot till a good portion of the pitch has come out and been scraped off, when the two coats of the leaf will be sure to keep out both the pitch and any discoloration.

INDELIBLE INK.—The French Government, it is reported, has just purchased the secret of the composition of an absolutely indelible ink—which resists the action of every known chemical agent. This ink will accordingly not only be used on all stamped paper in the postal service and the revenue service, but in the recording of all acts of the Assembly; it will also be sold with stamps in all the small shops.

SWEET FERN FOR TANNING.—Thousands of acres of land in Michigan are covered with a growth of sweet fern, which has hitherto been supposed to be worthless, but it has been found that for tanning purposes it is unequaled, and that it yields forty per cent extract, while hemlock yields but fourteen. It promises to be very valuable.

ARTIFICIAL LEATHER is made in accordance with an English patent by a mixture of one part of glycerine to three of glue. If flexibility is desired, hoiled linseed oil is added, if elasticity, a solution of caoutchouc. The mass is placed on a fabric and pressed, then washed with a solution of chrome alum.

TO PREVENT EBULLITION.—In order to prevent ebullition of boiling liquids a small fragment of sodium amalgam or of sodium tin, is added, when the solution is acid. The efficacy of these depends on the evolution of a small amount of hydrogen during the process.—*Dingler's Polytech. Journal.*

GOOD HEALTH.

The Value of Borax in Colds.

Dr. J. W. Corson, of Orange, N. J., has published some interesting notice on the use of borax and nitrate of potass, in aiding the voice, as sometimes required by singers, clergymen, and public speakers. The value of nitre, or sal prunelle, has long been recognized, and if it is increased by the aid of borax the fact is worth knowing. Dr. Corson sums up the result of his inquiries as follows:—

1. That in sudden hoarseness or loss of voice in public speakers or singers, from "colds," relief for an hour or so, as by magic, may be often obtained by slowly dissolving and partially swallowing a lump of borax the size of a garden pea, held in the mouth for ten minutes before speaking or singing. This produces a profuse secretion of saliva, or "watering" of the mouth and throat. It probably restores the voice or tone to the dried vocal cords, just as "wetting" brings back the missing notes to a flute when it is too dry.

2. Such "colds" may be frequently broken up at the very commencement; and this restorative action of the borax to the voice may be materially aided by promptly taking the evening previous to a public effort, dissolved in a glass of sweetened water, a piece of the nitrate of potass, or salpetre, a little larger than a garden pea, on going to bed, and covering with an extra blanket. The patient should keep warm next day. This both moistens the throat and further relieves the symptoms of cold and slight blood poisoning from suppressed perspiration, by reopening the millions of pores of the skin more or less closed by cold.

3. These remedies have the three recommendations of being easy to obtain, convenient to carry in travelling, and perfectly harmless.

USE OF COLD ABLUTIONS IN FEVER BY THE FRENCH.—In a valuable article contributed to one of the French medical journals by Dr. L'Ambert he presents the following conclusions concerning the use of cold ablutions in fever, as practised in France: They are especially useful in typhoid and the eruptive fevers, and strongly indicated in malignant cases. They act upon the chief and most constant phenomena of these diseases, are especially anti-febrile, and reduce temperature materially. They favor the re-establishment of a full, profound, regular perspiration; render the secretions more active; make the skin supple, moist and fresh, favor the outcome of the eruption; allay cerebral and other nervous excitement, suppressing headache, coma, delirium, restlessness and inducing sleep; cause the pulse to fall from eighty to thirty-beats. From two to eight hours is the duration of their action, the ablutions to be repeated two to four times in the twenty-four hours. They have no influence upon the length of the sickness, but render it milder, and are readily applied as cold baths or by wrapping the patient in a cold wet sheet.

CHLOROFORM IN CHINA.—According to a reported discovery by M. Stanislaus Julien, it appears that as far back as the third century of our era, the Chinese were in possession of an anæsthetic agent which they employed in the same manner as we use chloroform and ether, for producing insensibility during surgical operations. A description of this was discovered by M. Julien, in a work preserved in the Bibliothèque Nationale—called "Kon-kin-tong," or a "General Collection of Ancient and Modern Medicines," which appears to have been published in the sixteenth century. In a biographical notice of Ho-shao, who flourished under the dynasty of Wei, between the years 220 and 230 of our era—it is stated that he gave the sick a preparation of *chanvre* (Indian Hemp), "Mayo," who in a few moments became as insensible as one plunged in drunkenness or deprived of life; then, according to the case, he made incisive, amputations, and the like. After a certain number of days the patient found himself re-established, without having experienced during the operation the slightest pain. It appears from the biography of Ho-shao that this *chanvre* was prepared by boiling and distillation.

FURNACES FOR HEATING DWELLINGS should never be made of cast iron as is generally the case, for the reason that the unhealthy gases of combustion—carbonic acid and carbonic oxide readily permeate such iron when hot, and are thus distributed through the dwelling to the great detriment of health. The furnace should be made of wrought iron exclusively—hoiler iron through which when properly put together, scarce a trace of those deleterious gases passes. The expense is greater, but not sufficient to outweigh the health consideration. Wrought iron furnaces are largely supplying the place of cast iron ones in our Eastern cities. In cold countries, especially, this matter, as a sanitary question rises to great importance; and, indeed, it is quite time that more regard was paid as to the character of the air we breathe in our dwellings, school rooms and public buildings.

LEAD-POISONING.—A manufacturer of red lead, in France, saves his workmen from disease by obliging every man to drink a quart of milk a day. Instead of one-third of his men being on the sick-list, he has not had one case in eighteen months.

Reward for a Cholera Specific.

During the cholera epidemic of 1849, a prize of one hundred thousand francs was offered by M. Bréant, of Paris, for a specific remedy for that dreadful scourge. The attraction of this reward elicits every year most useful and interesting studies, but hitherto no one has solved the problem expressed in the following terms: Discovery of the means of curing the Asiatic cholera, or the indication of the precise causes of that dreadful disease. Every year, the Academy has to bestow some kind of encouragement on authors of very learned and useful memoirs on that question, but it is useless to say that not one has yet been found worthy of the principal prize.

Among others M. Tholozan, a military doctor, has been rewarded for his essay on the new origin of Asiatic cholera. He argues that cholera, although of Asiatic origin, may, nevertheless, begin and develop itself in Europe, and he instances the outbreak of 1852-1855, which spontaneously originated in Poland. This is a point of great interest, as it is a matter of much controversy among medical men of undoubted learning. M. Bouillaud, one of the Academicians, although disputing the accuracy of the author's conclusions, passed a well-deserved eulogy on M. Tholozan's researches, and summed up the Academy's sentiments on that question in the following words: There remains for our civilization the difficult but glorious task of tracking the monster to its cradle, or rather to its lair. We are still awaiting the advent of the *Hercules*, on whom will devolve the glory of so noble, so meritorious, so divine a work; but it is to be feared that in our day no such demi-god is likely to manifest himself.

KILLED BY KINNESS is a phrase which has just been luridly illustrated by statistics in England. Who would have believed, save upon the authority of the great Dr. Lankester, the London coroner, that not less than 3,000 tender infants are annually smothered to death by their mothers who fall asleep in bed while nursing their pledges? Unfortunately, mothers involuntarily kill their children in a great many other ways—by absurd indulgence in diet, by foolish exposure in dressing, and through utter ignorance of the laws of the human system. The only wonder is that the race, or at least the so-called civilized portion of it was not long ago utterly exterminated. Babies are called tender; it strikes us that they are remarkably tough.

REMOVING A FOREIGN BODY FROM THE NOSE. A case is related of a child from whose nose, when the surgeon had failed to remove a cherry stone, the village barber administered an emetic, and at the moment when vomiting was about to commence, clapped a handkerchief over the child's mouth, so tightly as to force the obstruction at once from its previously fixed location.

Another case is related where, under similar circumstances, an old negro woman advised: "Put yer finger 'long side the nose, t'other side from the thing, and with your own mouf over the child's mouf, blow hard, and ite bound to come out." The doctor followed the directions, with a favorable result.

WHEN BEGINNING TO USE GLASSES, use them as short a time as possible, only in deficient light, or on minute objects, and then change the strain to distant or larger objects. By a judicious attention to these two points, the age of the sight will be retarded many years. And as reading is one of the luxuries of the age, and one of its most delightful pastimes and amusements, we cannot be too careful of the eyesight, and should study how we may best husband its powers.

REMOVING AND RESETTING TEETH.—An English dentist recently had one of his teeth extracted, cleansed, caries removed from the crown and replaced in the socket, where it has taken fresh root. A dentist in Portsmouth, N. H., scientifically performed a similar operation some four or five years ago. We have a friend who submitted to a similar operation more than 30 years ago, and the tooth to-day is sound.

ENORMOUS BRAIN IN A BOY.—A boy, thirteen years of age, recently died in the Middlesex hospital, London, from injuries caused by a fall from an omnibus. His brain after death was found to weigh fifty-eight ounces, about eight ounces above the average male adult brain. The lad had been particularly healthy, without any evidence of rickets, and was very intelligent.

WHO REQUIRE MOST SLEEP.—Those who think most require the most sleep. Time gained from necessary sleep is not saved, but lost. Mind and body will both suffer. Most people, however, do not think enough to make early rising particularly dangerous. It is the hard-working professional man, the close student, or the man of business with many cares upon his mind, who suffers most from loss of sleep.

ZINC FUMES.—The action of zinc fumes upon the bones of the human system is very much like that of phosphorus. *Dental Cosmos* gives an account of the destruction of a large portion of a man's jaw bone by the fumes of zinc. The man was a brass founder, and was attacked by the zinc poison in pouring off the alloy zinc and copper.

Saturday Morning, Feb. 22, 1873.

Legal Tender Rates.—S. F., Thurs., Feb. 20.—buying 88½; selling 88¾.

Table of Contents.

GENERAL EDITORIALS.—A Munificent Donation to the Cause of Science; An Invention Wanted, 113. Mining as an Investment—Does it Pay? Giant Powder in Shallow Gravel Banks; Spectrum Analysis, 120. Ammonia for Domestic Use, 121. **ILLUSTRATIONS.**—The \$2,000,000 Diamond; Automatic Break Operator, 113. Pratt's Bed Lounge, 118. The Dwight Place Church, New Haven, 121.

MECHANICAL PROGRESS.—A New Process for Manufacturing Steel; What is Steel?; A Platinum Coinage; Cleaning and Refining Stone; A Triumph of Modern Engineering; Improved Car Axles; Steel and Magnetism, 115.

SCIENTIFIC PROGRESS.—Living a Science; Frost Crystals; A New method of Consuming Coal Smoke; A Novelty in Telegraphing; Light; A Beautiful Fungus, 116.

USEFUL INFORMATION.—Curiosities of the Boston Ruins; Durability of Wood; How to Clean Paint; Manufacture of Mad Stones; To Copy Manuscripts; Harness Dressing; Carbon Paper; Palm Wine; Removing Paint from Windows; The Babylonian Willows; Trellis Columns; American Implements in England; Killing Knives; Indelible Ink, 119.

GOOD HEALTH.—The Value of Borax in Colds; Use of Cold Ablutions in Fever by the French; Chloroform in China; Furnaces for Heating Dwellings; Reward for a Cholera Specific; Removing a Foreign Body from the Nose; Removing and resetting Teeth; Enormous Brains in a Boy, 119.

MINING SUMMARY from various counties in California, Nevada, Idaho, Montana, and Utah, 116-17.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 116.

CORRESPONDENCE.—Placer Mining Near Forest City, California at the Vienna Exposition, 114.

MISCELLANEOUS. Still Another Safety Gauge; Seam Mining; A Valuable Invention, 114. Resources of Utah—Some of the Principal Mines; Prospecting With Drills; Winter in the Mines, 118. Farming vs. Mining; The Richest Mine; A New Telegraph Cable; A Hermit Inverness; Stockton and Jones Railroad Co.; A Chance for Manufacturers; What Swan & Co. are Going to do About Packages, 122. The Australian Subsidy; New Incorporations, etc., 124.

UNIVERSITY LECTURES.—The seventh of the University course of lectures was delivered on Saturday evening last, by Prof. W. T. Welcker on the "First Ideas of Mathematics." The lecturer described the early progress of that science in the hands of the ancients, in a graphic, instructive and interesting manner, and was listened to attentively by a large and appreciative audience. The next in the course will be delivered this evening by Prof. J. LeConte on "The Ancient Glaciers of California."

THE AYERLL CHEMICAL PAINT, in addition to its cheapness and durability, is said to possess another admirable quality—the capability of being washed without injury to the paint. J. W. Tuoker & Co.'s building, on the corner Sutter and Montgomery streets, painted in December 1870, by Sweet & Gadsby and washed this month, is referred to by the company as one among the numerous instances of its merits in all respects as claimed above.

PROSPECTING COMPANIES are being organized at Pioche on the co-operative principle, some working for wages while others prospect or develop. They are all working men and combine their means and labor to become mine owners. A good move, this, for the miners, provided too many men are not let in to the companies so as to divide up the share to too great an extent.

SUTRO TUNNEL.—It is said that since the Committee on mines and mining reported favorably on the loan to the Sutro tunnel, that its chances are good to pass the House. It is hoped that the project will not fail for want of means.

A BILL has been introduced in Congress granting the right of way for the construction of a tunnel under Mere Island straits between that place and Vallejo.

Mining as an Investment—Does it Pay?

The above question, probably for the first time in the history of mining on the Pacific Coast, is now being seriously argued by many persons, who for years have devoted their time and their money, to the exploration and development of the mines of California and Nevada. Of course ideas widely differ as to the interest a mine should yield on the original investment and all the expenses connected with the development of the property, such as steam machinery, reduction works, etc., before it should be classed as a really paying concern. The people of this country, as a rule, are accustomed to pay, and expect to receive high rates of interest, and consequently they imagine that if a mine does not pay for itself in a year or eighteen months, that it is of no value; others whose notions are not quite so extravagant, are satisfied with three or four per cent. a month; now, while we are perfectly willing to allow a fair margin, for the extra risk attending all mining speculations, we consider that a well defined quartz vein, properly explored, and managed economically and honestly, which will pay from three to four per cent. interest is a far more desirable property to invest in, than any farm or piece of real estate in California, and since the Pacific railroad has brought us into such close competition with the more frugal and economical people of the Eastern States, we fancy that there are few importers or wholesale merchants in this city, who have not to content themselves with about one-half of the profits on their various risks, which they would expect had they bought a mine instead of a cargo of tea.

The production of bullion last year in the States and Territories on the Pacific Slope was enormous, notwithstanding many drawbacks, such as a lack of reduction works, quartz mills, etc., in many of our new mining Districts. The amount of gold and silver produced will add up about \$62,000,000. And yet people in this city are strongly prejudiced against mines and say they are so risky, that they don't pay, and there is so much swindling going on, and etc. When we have a dry season in California and the wheat crop fails, which by the by, occurs oftener than is pleasant. There is no outcry about farming not being a paying business; when a ship with her precious freight goes to the bottom of the ocean, instead of bringing up safely in port, the owners hear their losses most philosophically, build another ship, buy more costly wares, and again trust all to the mercy of the winds and waves, and we never hear a word of complaint about merchandizing or shipping being a non-paying business. It would seem as though people reserved all their ill-humor and indignation for unfortunate mining speculations. When a man through carelessness and ignorance rushes blindly in, and purchases a worthless mine, of course he loses money; he should have availed himself of the knowledge of those who have made geology their study, and have been fully assured of what he was doing before he invested a dollar. But such a one is rarely willing to attribute his want of success to the proper cause; it is always on the mine, and on mining investments generally that the vials of his wrath are poured out. It is true he might have been swindled out of legitimate profits, even had he invested in a good mine. And if he risked his money in Washoe mining stocks, the chances are that a rescallo board of trustees would not only have confiscated his dividend, but have levied a heavy tax, in the shape of assessments on him, into the bargain.

But as he went in, for a little gambling in stocks, he must not complain, if he was beaten by those men who make such a pursuit their sole business; he may console himself with the reflection that he has many companions in his misfortune, both at home and abroad. Even in far distant England, they complain of having been swindled, on wild cat mines, still, when we come to investigate facts, we find that English companies at present own more dividend-paying mines in California and Nevada, than are quoted on the list of the San Francisco stock board.

The number of mines worked legitimately in this country is greater than many people suppose, and let any person at all conversant with the subject, take a trip through Amador, Nevada, Sierra and Plumas counties, to-day, he will find one hundred mines, the names of which he probably never heard of, yielding handsome dividends to the stockholders.

It would occupy too much space in this article to go into statistics, or enquire what such quietly managed companies as the Keystone, Amador, Kennedy, Mehoney, Idaho, Eureka, North Star and Sierra Buttes had yielded the owners; of one thing, however, our readers may

be assured; viz.; that there are plenty of such mines lying idle to-day in California, which can, and yet will be profitably worked, when the swindling hitherto practiced by a few California street stock operators, shall be counteracted by a little common honesty in mining management.

Giant Powder in Shallow Gravel Banks.

A correspondent writes us from Oregon in relation to the use of Giant Powder for bank blasting in shallow gravel mines. He wants to know whether the use of the powder facilitates work in gravel mines of not more than 18 or 20 feet in depth, the gravel being what miners call a "tight" or semi-cement intermixed with a tenacious or putty-like clay. The gravel and clay are not, properly speaking, intermixed, but alternate, or the clay will overlap the gravel. He tells us that he has a great many rocks or boulders to contend with in his claim, and asks "if the powder should be used in such a claim, what is the *modus operandi*, that is, is it better to drive a horizontal or a perpendicular hole?"

In answer to our correspondent's queries we would state that in shallow gravel benches, in pipe clay and cement, No. 2 Giant Powder is used with perfect success. Whether the holes should be horizontal or vertical, depends considerably on the face and shape of the bench, and the work required.

If the face of the bench be "squared up," a series of vertical shots, fired with electricity, will throw up, and pulverize, the bench. The same is true of horizontal and angling shots in working up the bottom. A few experiments in a claim will decide which are the better shots to put in. In breaking boulders (if very hard), small drills, cutting ¾ inch holes, and 3½ pound hammers are of great advantage, used in connection with Giant Powder, of either grade, though the No. 1 is more preferable—one man doing twice the work of two men with large drills and black powder. The method of loading bore-holes we have previously described. The cartridges, however, should be as near as possible, the size of the drill-hole; the Company make them from ¾ of an inch to 6 inches in diameter. It is somewhat difficult to lay down rules as to which kind of shot to trust in, unless the character and situation of the ground is known; but, as remarked before, a few experiments will show which is best.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening, when James Lick and George C. Hickox were elected life members and Gregory P. Hart a resident member of the Association.

Donations to the Cabinet.

A specimen of hornblende, containing 20 per cent. of magnetic iron, from the Chilcat River, Alaska, was presented by Professor Davidson.

Captain G. T. Lawton sent to the Academy, fossil bones of a rodent, from a drift of the Eureka Consolidated mine, in Nevada, found 247 feet below the surface, near the top of the ore, and immediately under the hanging rock of limestone; a specimen of silver ore from the same mine was received. Among the other contributions was a fossil from the Arizona Desert, a specimen of fish lice from the fish in San Francisco Bay, the head of a black-tailed deer, and some worm-eaten piles from Greenwich Dock, destroyed by the new marine worm which has recently made its appearance in our harbor. The worms were seen attached to the pile. T. J. Arnold, engineer of the seawall, was under the impression that the worm is the *limnoria terbrans*. Dr. George Hewston read a paper on the subject of marine worms referring particularly to the one in question.

The Academy received a handsome gift of a lot of land from Mr. James Lick, which is referred to at length in another column of this issue.

Miscellaneous Business.

The President, Professor Davidson, read a paper "On the Probable Periodicity of Rainfall," which we will give with appropriate diagrams next week.

A gentleman, who proposes to read a paper on the possibility of inducing rainfall by artificial means, asked permission to do so, which was granted.

Mr. Dall, of the United States Coast Survey, read some interesting notes and memoranda on different birds noticed in Alaska, during his visits to that Territory.

After some discussion relative to the condition under which Mr. Lick's gift was made, the Academy adjourned.

Spectrum Analysis.

An important and interesting series of lectures was inaugurated on Wednesday evening last, by Prof. Neri, in the Hall of St. Ignatius College, on "The Spectroscope and Spectroscopic Analysis." Being introductory, it was somewhat elementary, but highly interesting and instructive, and was fully illustrated with experiments, as, indeed, each of the succeeding ones of the course—five in all—will be, aided by the elegant and expensive apparatus connected with the institution named. From the tenor of this, we think the public may anticipate something of rare interest and merit; and on a subject which is attracting a larger amount of interest than any other matter now before the scientific world.

Though the introduction of the spectroscope dates back but little more than a decade, we already find it used for manifold purposes, not only in scientific investigation, but also in industrial and useful arts as well. It has given us important revelations with regard to the constitution of blood and many other very deep substances; it greatly aids the geologist in many of his investigations; it is a most perfect and convenient medium for detecting adulterations in food; it aids the assayer at almost every step in his tedious and difficult works of analysis; and the lecturer was informed, just as he took his place on the stand that it is now used at the English Mint in London, as a most delicate test and check upon the several modes of assays employed there.

Spurning the narrow limits of earth, the spectrum goes out into space and undertakes to analyze the heavenly bodies; and by it, questions left unanswered for ages are now readily solved. It has made known to us the nature of the colored stars—a puzzle for ages. The character of comets and of nebulae are by it quite fully unfolded, and it is employed to measure even the motions and velocity of the most distant orbs whose light can be enticed within its magic influence.

The lecturer proceeded to give some idea of the ordinary modes and analysis, by both the wet and dry way, in order to show how the spectrum may be and has been brought to hear upon such investigations. His exhibitions of the various colored flames appeared to interest his auditors very much, and though simple and elementary in character, should be kept in mind to aid the hearer in understanding the future lectures of the course, during which the Professor will explain, step by step, with appropriate illustrative experiments, the introduction and progress of the spectrum in the history of science and the arts.

The electric current was introduced and the nature and connection of its use in spectrum analysis explained. The fact, that various colors may be given to the electric current, by the employment of different substances to form the positive pole of the battery was shown. The importance of this fact in connection with spectrum analysis will appear in future lectures. Some beautiful experiments in this connection were shown by sending the electrical current through various series of Geissler's tubes, in which the same current was made to assume, in its different sections, various colors during its transit through those tubes, charged with gases which gave off the colors shown when raised to the point of incandescence by the passage of the current.

This series of lectures will prove a rare treat to our citizens, and it may be mentioned that this is the first opportunity, out of actual school instruction, which the people on this Coast have had of becoming acquainted with the nature and value of the spectrum, and its various uses. The next lecture will be given on Monday, the 5th of March.

A LESSON TO "SALTERS."—The miners at Georgetown, Col., went to rely on the ore in their mines as it is, without any assistance from outsiders. They have every confidence in being able to sell what mining property they want to, without resorting to dishonest means to enhance its value in the eyes of speculators. At the same time the reputation of the country must be preserved. With these facts in mind they gave a very appropriate lesson to some dishonest miners who were caught salting rock with chloride of silver. They took two of the men, put ropes around their necks and after choking them until they were nearly dead, turned them adrift. The Denver News, which tells the story, says the assay value of the ore was 42 ounces per ton, while the salted sample returned 330 ounces per ton. If this course had been pursued to any extent in the mining localities, while the reputation of the camps would have been bettered, the population would have decreased considerably.

THE SNOW in Little Cottonwood Cañon, Utah, is still very deep and there is great danger of slides. The miners of Nevada county, Cal., are laying off, because the snow has closed up the ditches and shut off the water.

Artificial Stone for Building and Other Purposes.

Availing ourselves of a pleasant day this week, we paid a visit to the Frear Stone Works on Bluxome street, between Fourth and Fifth, and near the freight depots of the Central Pacific Railroad. Judging from the amount of stone-work we saw in the buildings the company must be doing a pretty good business. The premises occupy a space of 300x120 feet, upon which are erected a number of one-story buildings, all connected together, and divided up into different apartments. Large bins for storing the sand and gravel used in manufacturing the stone are filled with the substances, the former of which is procured from Oakland har. The sand is used in a natural state, no melting or crystallizing being done.

The patent under which the Frear Stone Company operates is on the chemical solution which is mixed with the sand or gravel. The facing of the stone is made of fine white sand, and the back portions of sand and gravel mixed. This facing sand is all selected, so as to be free from iron or other impurities, and is then thoroughly dried and sifted to eject the natural moisture. This care enables them to get a fine surface to their work. The process of manufacture is exceedingly simple. The sand after being dried and sifted is dampened so that it will hold together, with the patented solution. A certain proportion of Portland cement is ground fine and mixed with it, and the whole is stamped into moulds previously prepared. After the mixture is pressed in sufficiently it is removed from the mould and set aside to "cure." After a few days "curing," the stone is perfectly solid, but the Company prefer to keep the work at least six weeks, so that there will be no danger of breakage. There is on the premises a vat for drying the same, and a few small mills for grinding and sifting the cement. After the mixing is perfected the material is carried to the moulding room, and from thence in its proper forms to the drying rooms. The company make their own patterns and have a shop set apart for the purpose. So that if any one desires any particular design of any kind whatever, he can have the pattern made to suit him, and the stone will be moulded in the desired form. In making the moulds the patterns are set inside of a heavy box in all cases and the mould set inside of that.

They are now engaged in making a number of burial cases in which coffins may be placed, and the cover of the case secured with cement, thereby preserving the contents from the attacks of moisture or air. A number of urns of different sizes, as well as fountains, are being made, and also several pedestals with the appropriate names upon which the marble statues at Woodward's Gardens are to be placed. Considerable fence and cemetery work is being done, horse blocks, building material, ornamental work, etc. There is a large amount of Portland cement in the warehouse and more is on the way. At present 20 men are employed. They calculate to furnish the Frear Stone for one-third less for ornamental building and plain work, than is charged for natural sandstone, and for less than half the cost of finished granite.

This stone is now coming into extensive use in this city and elsewhere. Beside the stone used in ornaments on the Niantic Building and Tallant's New Bank, Bartlett's Block in Oakland, three stories high, has the whole front made of plain solid Frear Stone. We saw at the office of the Works, photographs of a number of buildings which have been erected in New York and Chicago, which show the elaborate designs which may be adopted. There is a piece of stone at the Works, which was under the effects of the Chicago fire, which shows no signs of having been subjected to heat. The Works in this city have only been under way since last August.

The experience of the Chicago and Boston fires has done much to turn the attention of the public to the necessity of fire-proof building material; for what was supposed previously to be fire-proof, failed at the moment when these properties were most necessary. Granite, which everybody considered as a barrier to fire, flaked off in large pieces during those conflagrations, and both brick and sandstone crumbled before the flames. The Frear stone, however is said to have stood the test admirably, as numerous statements verify. Merrill Ladd, Esq., President of the Mutual Insurance Company of Chicago, writes as follows: "In passing through the 'great fire' no signs of flaking, splitting or disintegration were perceptible, as was the case with all natural stone (even granite) which was used in this city. I will say, in conclusion that I believe Frear Stone to be the best material that can be used for building where strength, solidity and protection against fire, are desired." Dr. Adolph Ott, in a lecture on "Portland Cement and Portland Cement Stone," read before the Polytech-

nic Club of the American Institute, and published in the *Industrial Monthly* some months since, includes the Frear Stone among the Portland cement stones and says: "To any one acquainted with the chemical composition of cement stone, it must at once become evident that, with regard to its resistance against fire, it ought to supersede most building stones."

The company manufacturing Frear Stone in this city is incorporated under the laws of the State of California and although the product has not been invented long enough to prove by practice its efficacy against the ravages of time

and atmospheric influence, it has successfully borne severe tests of scientific skill. Instead of the action of the moisture of atmosphere, it has been subjected to immersion in boiling water and the steam bath, without change or injury. It has been tested in a furnace instead

of stent parts; adhesiveness of the cementation; non-liability to fusion or disintegration by fire. Since with all these advantages it can be made so cheaply and so rapidly, whatever the design, it is destined in the future to take a large part in the construction of edifices in cities and towns. In the country it can be made on the spot, provided sand and gravel is to be found in the vicinity.

The illustrations shown on this page represent two buildings constructed of Frear Stone; the lower one shows the Dwight Place Church, at New Haven, Conn., and the upper one is

"THE HALE BUILDING," CHICAGO.

the Hale building, a five-story structure 90 feet by 100, which is in Chicago. The entire stone-work of the church was made from sand excavated from the foundation and formed into artificial stone by the Frear process. It is stated that the cost was one-third less than if it had

CHURCH AT NEW HAVEN, BUILT OF FREAR STONE.

of in the sun. Instead of the corrosive gases of a manufacturing town, using coal for its fires, it has been placed in a bath of sulphuric acid. Instead of being placed in buildings to sustain a crushing pressure, the pressure has been mechanically applied, of 57,000 pounds on a four-inch cube at the age of four weeks. The following advantages are claimed for it: compactness in combination with the character of the constituent ingredients; freedom from metallic mixtures; uniformity in its structures and con-

struction; adhesiveness of the cementation; non-liability to fusion or disintegration by fire. The style and finish of the exterior is very effective, the details being elaborately worked and in perfect harmony with the general architectural designs.

The Hale Building, in Chicago, has an imposing front, in modern style, and makes a very handsome edifice. The Frear stone is playing quite an important part in the reconstruction of Chicago, and is highly commended by the local press.

PATENTS & INVENTIONS.

Telegraphic List of U. S. Patents Issued to Pacific Coast Inventors.

[REPORTED OFFICIALLY FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Despatch, Dated Washington, D. C., Feb. 18th, 1873.

FOR WEEK ENDING FEBRUARY 4th, 1873.

CANTEN.—Richard Kelly, Red Bank, Cal.
CAR STAKE SUPPORTER.—Wm. H. Masterman & Wm. T. Hooper, Stockton, Cal.
PEO RASP.—Jeremiah W. Foard, S. F., Cal.
FINGER BAR FOR HARVESTERS.—Chas. A. Smith, Napa, Cal.
CURING TOBACCO.—James D. Chup, Gilroy, Cal.
RAILWAY SNOW PLOW.—W. Walker, Fort Bridger, Wyoming Territory.
BLACK BOARD ERASER.—Winfield S. Read, Oakland, Cal.
HARVESTER CUTTER.—Warren Wasson, Phineas F. Powers, Geo. W. Duogan, of Genoa, Nevada.

DESIGN.

CENTER PIECE.—Samuel Kellett, S. F., Cal.

TRADE MARK.

I. X. L. METAL CO.—Anti-Friction Metal and Journal Bearings for St. Louis, Mo., and Sacramento, Cal.

Following is a list of inventions patented in England by inventors in the Pacific States and Territories from Aug. 6th to Dec. 31st, 1872:

WASHINGTON ORES.—W. Rickard, Monitor, Cal. Dated Aug. 28, '72.
UTILIZING HYDROCARBONS, ETC.—Perry Franklin Goodrich, S. F., Cal. Dated Dec. 3, '72.
RAILROAD COUPLING.—H. Clay Kihhe, S. F., Cal. Dated Dec. 6, '72.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

Ammonia for Cleansing and Other Uses.

The uses to which ammonia can be put are extending daily, as its value becomes better known. This is the case not only in the arts but in domestic economy where its varied applications are beginning to make it recognized as a valuable article. The liquid, ammonia, plentifully diluted is found to increase the growth of house plants, and as a cleanser and purifier it stands paramount. The fact that fatty and greasy matter saponifies with ammonia is taken advantage of in many ways. By adding a little to warm water, paint can be washed thoroughly and much easier than with soap alone. By the addition of a teaspoonful to a basin of water for bathing, it is softened and imparts a delightful sense of coolness after washing. It will clean hairbrushes, etc., most effectually by dipping them in a solution of warm water and ammonia; will cleanse cutlery, carpets, crockery, glass and floors. A few drops on a window-pane will clean it as bright as possible, and much better than water alone.

From whatever place grease spots are to be removed, whether from the floor, paint, woolen or other fabrics, it is very convenient. Ammonia has been used with good effect in curing poisonous bites, such as those of snakes, etc. Mixed with oil it is used as a soap, under the name of soap liniment. Experiments are being made with it as a motive power from the fact it only employs 126 units of heat in its expansion, while water absorbs nearly five times as much heat. The common liquid boils at 122° and affords a pressure of six atmospheres at 232° F., while steam requires a heat of 320° to produce the same results. It is said that ammonia prevents iron from rusting although it acts on copper and brass. We understand that ammonia for washing and cleansing purposes is being manufactured in this city in quantities and is being sold by the retail grocers, so we hope there will be no future necessity for further importation. When people become more accustomed to use it, they will realize the benefit to be derived from it to a greater extent. The article made here is intended in a measure to be used for washing purposes, and there is every reason to be assured that it will aid materially in cleansing clothes. It is universally used in Europe for every-day family use and if offered at proper prices here, so as to bring it within reach of every household, will rapidly come into favor as it has elsewhere.

A 15-STAMP MILL is between Fort Yuma and Hardyville, on its way to Sacramento District, Arizona.

Farming vs. Mining.

An important suit has been on trial in Oroville during the three weeks past, involving the liability of miners for damage done to farming lands by means of mining debris washed on the lands from mining claims above. The plaintiff is a farmer on the bottom lands on Dry Creek, in Butte county, eight miles below the hydraulic mines of defendants, which are located on Sawpit Ravine, and sued defendants to recover \$2,000 damages for injuries to his farm by reason of the deposit of debris from defendants' tailings, and also for an injunction to put a stop to the mining operations of defendants, a continuation of which, it was alleged, would result in the destruction of plaintiff's farm. The testimony showed that the injury would have been the same had the defendants not been engaged in the business of mining; that the damage resulted from the action of fifty or more companies, and the jury were, in consequence, unable to find the exact proportion of damage committed by the defendants, the result being a substantial acquittal of the latter and a denial of redress to the plaintiff. The Marysville Appeal says of this case:

Probably no mining suit ever before tried in this State has attracted more universal interest among miners, who have been represented at the trial from nearly all of the mining districts throughout the State, some having been subpoenaed as experts and others attending out of curiosity and personal interest. While the verdict does not decide that mining companies are not responsible in damages for injuries to the lands of farmers by depositing tailings upon their lands, it yet discloses so many difficulties in the way of arriving at the question of liability, and the relative responsibility of the numerous companies that jointly contribute to make up the aggregate of such deposits, as to show that the farmer can have but little show in making out a defined case that will secure him damages. In the present instance the verdict is very generally sustained by public sentiment. It was shown in evidence that over a million dollars had been spent by the mining companies interested in the issue; that having perfected their works at enormous expense, they were now prepared to reap the reward of their enterprise, and that the probable yield of these mines was estimated at from \$50,000,000 to \$100,000,000. A single day's yield of the precious metal, judging from what these mines have heretofore produced, would amount to more than the value of every farm that could possibly be effected by their operations.

It was in evidence that plaintiff's improvements were of the value of \$2,500. If the statements of the relative value of the mining and farming property are correct, and if, as appears from this testimony, the mining operations whose results were complained of were under way prior to the occupation of lands below for tillage, in the knowledge of plaintiff, the finding of the jury is in substantial accord with the larger equities of the case. Abstractly, it is a matter of great regret that any person who has made a home on a piece of land, planted and beautified it, should be a sufferer from mining operations near him. But it must be remembered that public policy has allowed the use of stream channels for such operations for twenty-three years, and that in such cases as the above, mining had been going on almost exclusively for a greater part of that period. Such instances of injury to garden and farming lands are much less frequent now than some years ago, and will be still less frequent hereafter, with the diminution of the placer mining area, the better enforcement of the recognized rights of prior occupation, and the general operation of the system of ownership in fee to the mineral lands, which is being accomplished under the recent legislation of Congress. Public sentiment in the mining regions is more just to the agricultural interest than of old. This interest is seen to be of great value, is often in alliance with mining, and assists largely in bearing the burdens of taxation and making a residence in the mining regions not only more endurable but positively attractive. Hence it is not to be expected that any gross injustice to the cultivators of mineral soil will be tolerated, and in cases like that tried at Oroville, the decision is against them, it will be on the ground of consideration for the rights of the larger number who were first to begin their industry.

THE RICHEST MINE.—In a San Francisco paper of last week we notice the following item: The noted Gwin mine of Lower Gulch, Calaveras county, is now yielding more gold than any other mine in the State with the same milling capacity. The clean up last Sunday, after a run of six days with 36 stamps, resulted in obtaining \$9,160—a yield of over \$1,500 per day.

The Call, from which the above item is taken, is evidently not posted upon Grass Valley mining matters. For its special benefit we would, therefore, intimate that the Idaho mine, in Grass Valley, running 35 stamps, for six days, cleans up, from its amalgamators and plates alone, an average of \$20,000, or over \$3,000 a day, and the Enreka mine, with ten stamps and a run of six days, has been cleaning up \$12,000 or \$2,000 a day.—Grass Valley Union.

A New Telegraph Cable.

A correspondent of the *Alto* writes as follows from Washington under date of Feb. 3d: Signor Celso Caesar Moreno, an Italian gentleman who has resided many years in China, is here representing the interests of the American, Japan and China Telegraph Company. A consideration of his project must be of interest to the people of the Pacific Coast, whom it is especially intended to benefit. The company was originally called the American and East India Telegraph Company. Its charter is obtained from the State of New York. It is organized with a nominal capital of \$10,000,000, representing 200,000 shares of \$50 each. The officers are as follows: President, Dudley J. Gregory, of Jersey City, New Jersey; Vice-President, Josiah Oakes, New York; Treasurer, Wm. F. Stearns, New York; Secretary, Chas. D. Kellogg; Directors (including President): Samuel W. Torrey, Esq., Hon. D. D. T. Moore, Maunsel B. Field, Esq., Joseph T. Sanger, Esq., and Wm. H. Waring, Esq., of New York; Hon. George N. Kennedy, of Syracuse, N. Y.; Hon. John A. Goodwin, of Lowell, Mass.; John N. Knapp, Esq., of Auburn, N. Y.; Hon. Samuel G. Arnold, of Providence, R. I.; and C. S. Bushnell, Esq., of New Haven, Conn.

This Company propose to lay a telegraphic cable from San Francisco to Japan and China by way of the Aleutian Islands on the north, or the Sandwich Islands to the south. The route will be chosen in view of practicability and economy hereafter to be determined. It will be seen that little is asked in aid of the enterprise by reading the text of the bill introduced in the Senate April 10th, 1872, by Mr. Frelinghuysen, and referred to this Committee on Foreign Relations. It is as follows:

A Bill to encourage and Promote Telegraphic Communication Between America and Asia.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress Assembled, That the American and East India Telegraph Company (the name to be changed to the American, Japan and China Telegraph Company,) shall have the right to construct, land and maintain a line or lines of telegraph or sub-marine cable on the Pacific Coast of the United States, to connect the American and Asiatic Coasts by telegraphic lines, wires, or sub-marine cables: Provided, That said company shall begin to lay said cable within two years from the passage of this Act.

Sec. 2. That in order to encourage and aid in the construction of said line or lines of telegraph the Secretary of the Navy shall detail, for the surveys and soundings on and along that portion of the Pacific Coast in America and Asia where it is proposed to establish said telegraph lines, one or more steam vessels, to be at the disposal of said company, to assist in surveys and soundings, laying down and summing of cable, transporting materials connected therewith, and generally to afford any assistance calculated to promote the success of the enterprise.

Sec. 3. That the Government of the United States shall at all times have priority in the use of the lines of said company for all diplomatic and Government business; and in order to secure the same from injury by evil-disposed persons, to the interruption of public business, the Secretaries of the Navy and of War are authorized to direct the commanders of military and naval districts or stations traversed or occupied by the stations or lines of telegraph or cable belonging to said company, and other officers acting under the authority of the United States, to use any force at their command to protect the same. Said lines of telegraph shall be open at all times to the public, and to any other company, upon the payment of the regular charges, for the transmission of dispatches, excepting when in use by the Government of the United States.

Sec. 4. That the better to promote and facilitate international intercourse and the public interest, Congress may at any time repeal this Act for neglect on the part of the company to fulfill and comply with the conditions herein expressed.

Sec. 5. This act shall take effect immediately.

The Scheme is American

In inception, organization and prospective profit. The company appeals for aid in the manner above shown, stating in eloquent language the necessity we labor under of looking to the Pacific for a revival of our commerce. They ask for no subsidy whatever—only the use of Government ships in making soundings preparatory to commencing the work. They say: "The impossibility of consummating such a scheme without governmental aid and protection is too apparent. No capital could be procured without such aid, and we could not ask for less than we do. But for such aid to Morse in March, 1843, the world might still be without telegraphs."

The Prospects

Seem favorable for Signor Moreno's success, although little time is yet at the disposal of Congress. The bill is before the Committee on Foreign Relations in both houses. It may not pass at the present session for want of time, but attention has been sufficiently drawn to the subject, so that at the next session at least, it is to be hoped, something will be done. It is not improbable, however, that success may attend the efforts of the company this winter.

A Hermit Inventor.

The *Territorial Enterprise*, of the 7th ult., says:

In a lone cabin among the hills to the eastward of this city lives John Duhois, a man full of eccentricities and a genius in his way. In his cabin, far away from the noise and bustle of the town, he leads the life of a hermit. He is a good mechanic, and always at work upon some new invention. Among the inventions he has completed, is a windlass of peculiar construction, for use in mining, which is said to possess many advantages over everything of the kind heretofore produced. He has also invented a car for use in the mines which is said to be far superior to anything now in use. It can be managed by a boy ten years of age, and dumps either over the end or the side, without the least danger of its being thrown off the car-track. For this invention we believe he has applied for a patent. His great machine, however, is some sort of contrivance for the multiplication of power and speed. He has been at work on this for years, and has at last brought it to perfection and obtained a patent on it. What the machine is like we cannot say, as we have never seen it, but the gentleman who furnishes this curious genius with provisions and other necessities, says it is a most ingenious contrivance and will do all that is claimed for it. According to his description, all the machinery is on a single shaft, and the apparatus for multiplying power and speed is contained in a drum or cylinder that surrounds the shaft. The first machine of this kind was somewhat rough, and he destroyed it, after finding that it would work, and has since made one with which he has taken great pains. He is satisfied that he has half a dozen fortunes in his several inventions, had he sufficient means to bring them into notice. Here is probably a chance for a man with a few thousand dollars to make himself a millionaire and equally enrich the old hermit-inventor.

STOCKTON AND IONE RAILROAD CO. — A despatch to the *Chronicle* states that on the 13th inst. the articles of incorporation were filed in the office of the County Clerk of San Joaquin county, for the Stockton and Ione Narrow-gauge Railroad, with E. S. Holden, President; H. E. Hall, Secretary; E. R. Stockwell, Treasurer, and nine of the most substantial men in landed interests and business relations in this section of the country as Directors. A liberal sum has already been subscribed, and many large subscriptions have been awaiting the opening of the books, which has been very magnanimously deferred until the formation of the San Joaquin and Tulare Company, so as not to interfere with that project, which, being assured, removes all further delay.

The work will commence upon this new project at the earliest moment. Dr. Holden, the President, is the principal organizer of many railroads and agricultural projects in California, and under his management the Stocktonians feel jubilant over the success of the enterprise.

A CHANCE FOR MANUFACTURERS. — A correspondent of the *Bulletin*, writing from Healdsburg, Sonoma county, says: The people here are much interested in the subject of establishing some kind of manufacturing industry of character and importance at this point. Near the base of Fitch mountain and close to the town, is a splendid water-power which can be utilized at a comparatively trifling cost, and made serviceable for manufacturing purposes. This, John D. Hassitt proposes to donate to any one who will start a manufacturing enterprise here—together with all the necessary ground for building purposes, etc. In addition to this, the citizens will donate several thousand dollars. The raw material for certain kinds of manufacturing can be had here in abundance. We have a climate scarcely surpassed in the world, and the soil the most prolific, and never failing to yield abundant crops to the industrious man.

RAILWAY ACCIDENTS.—Since last February the *Railroad Gazette* has made up monthly exhibits of railway accidents occurring in the United States, giving their nature and causes, as nearly as could be learned, and the number of persons killed and injured. The number of accidents for December is 412, which is larger than yet reported for any single month. The attending fatalities were 42, but this number was exceeded in June, on account of the Grand Trunk disaster. The number injured, but not fatally, yet reported. Sixteen of the 112 accidents caused death, and 28 other injuries to persons; and, therefore, 68, or about three-fifths of the whole number resulted in injury to property only.

RAILROADS IN THE MINES.—The Salt Lake, Sevier and Pioche Railroad Company will have forty miles of road completed by next June, making connection with steamers on Great Salt Lake, twenty-two miles from this city, running thence to Stockton, in the heart of a rich mineral district.

THE new locomotive for the Pioche and Bullionville (Nevada) Narrow Gauge Railroad has been shipped from Lehi, and it is now confidently asserted that trains will be running over the road before the expiration of the present month.

THE FLORAL MILL at Pioche has been completed and is now ready for use.

What Swan & Co. are Going to do About Packages.

In investigating the box question we had occasion to call at the Union Box Factory, No. 114 and 116 Spear street. This is a large establishment, 92x137½ feet, and the proprietors have been a long time at work introducing new machinery and new methods for reducing the cost and improving the quality of all sorts of packages.

Their improvements rest upon slicing timber instead of sawing, and an impervious coating by which they can make a wooden box hold anything.

By means of two large knives sliding in gates they can cut timber into slices from 1-64 to ½ an inch thick, and leave it as smooth as writing paper. Thus they save the timber formerly wasted in sawdust and chips, and the time and power necessary to make the sawdust and chips. By furnishing wood so thin it can be used instead of pasteboard, and the same weight and thickness of material makes a stronger, stiffer, better box. It can be covered with any kind of fancy paper for a finish. This impervious coating enables them to use wood instead of tin with the advantage of a non-conductor of heat, no rust and no taste. One man wants 100,000 lard caddies, and they are constantly being adapted to new uses as coffee boxes, pickle jars, jelly boxes, etc. They can be made round, square, octagon or any shape you wish.

Peach Baskets at Half the Old Price.

These are made light, neat, nesting nicely and at half the price that any others can be sold. Like everything else made from sliced stuff they can be shipped in the flat, so as to take up no more room than so much solid timber, and can be put up where they are used.

Boxes for Plums, Apricots and Cherries

Have been very extensively used the past year and furnished at thirty per cent. less than old prices. Their use has demonstrated the fact that the principal strength of the square box depends upon the pieces that hold the nails. If only the ends are strong the top, bottom and sides may be quite thin. These are generally put up where used.

For Berries,

He furnishes four or eight-pound drawers suitable for slipping into common chests at \$25 to \$30 per thousand. These are sent in the flat and can be put up very rapidly by almost any boy or Chinaman. He is also experimenting with a package greatly in favor in Chicago, as a one and two-pound basket. It will be very cheap and very light.

Grape Boxes

Are made similar to strawberry drawers, save that they have a cover which turns back so that the fruit can be shown without drawing any nails. An extensive experience in shipping grapes to the New York and Boston markets, in different kinds of boxes, convinced us that the most money was to be made by shipping in as small a box as would answer to pack grapes nicely without cutting the clusters. The fruit reaches the table in much better order from the original package than when taken from a large box, weighed and sent home in a bundle.

All these light boxes have corners made by scoring half way through the wood and bending it. We think something similar to this box will be used for all kinds of dried fruit, figs, raisins, etc. Fruit drying companies, as well individuals, will do well to turn their attention in this direction.

Wooden Boxes for Pickles and Jellies.

The use of this coating which makes the wooden box impervious to any liquid and tasteless, renders it the very thing for jellies, pickles, and a thousand household uses which will develop themselves in future. The wood ready cut for any style of box can be sent anywhere with the preparation for coating it, so the matter of freight cannot operate against their general introduction. Merchants can keep a large stock of this kind of goods in a small space and have work for the boys at odd spells.

Butter Chests

Are made here by the use of improved dovetailing machinery, so cheap that other box makers can do better to buy of Swan & Co. than to make them at home. The same machine that dovetails these is used for making tool-chests, bullion boxes, and anything that requires to be very strong. It makes the ordinary dovetail.

The Mitre Dovetailing Machine,

Is quite a curiosity and makes a wonder of a box, both as regards neatness and strength. It cuts a groove in the end of the box, and a tongue in the side to slip into it so that a very strong corner is made, and you must knock off the top or bottom to see how it is done. It is used for fancy boxes ¾ of an inch thick and upwards.

Farmers' Clubs will do well to send for samples of these various styles, as Mr. Swan has kindly offered to send samples free to such organizations. It might be too much to ask him to send a butter chest without any pay; but he is a very liberal man and will do anything reasonable.

San Francisco, Feb. 20th, 1873.

UTAH MINES.—The snow hockade at Little Cottonwood is broken, and ore is coming down on pack animals. It is estimated that there are over 5,000 tons of ore on the dumps waiting for transportation.

DEWEY & CO.,
American and Foreign Patent
Agents, Publishers of the
Mining and Scientific
Press, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chile, Argentine Republic, and EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applications which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency. The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by the extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

Varney's Patent Amalgamator.
These Machines Stand Unrivaled.
For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.
The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plate again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.
Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.
Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

Richardson & Co., Copper Ore Wharves, SWANSEA.

RICHARDSON & Co. have been for thirty years established in Swansea as Agents for the preparation, Sampling, Assaying, and Sale of Copper, Silver, Gold, Lead, Zinc, and all other Ores and Metals, for which they have extensive Wharves and Wharves under cover, 1,000 feet of Quay Frontage within the Floating Dock, and the most complete Machinery and Appliances. They are also prepared to make advances against Ores in anticipation of realization, and to guarantee all payments when required. 11v24-1y

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 125 First street, S. F. 24v25tf

BURLEIGH ROCK DRILLS

—AND—
Air Compressors.

The Burleigh Rock Drills, which have stood the test of five years' constant use at the Hoosac Tunnel, and which are now in use in nearly every State in the Union, as well as in Europe and South America, are unequalled in efficiency and economy by any other Drilling Machine. They are of various sizes, and equally well adapted to Tunneling, Shafting, Open Cut or Quarrying, and will drill six to ten inches per minute in granite. They are driven by steam above ground. The Burleigh Air Compressor is the best engine yet devised for furnishing the "air motor" for the many purposes to which it is now being used.

They are to be used on the St. Gothard Tunnel, Switzerland; Tunnel 13 miles long. We refer to the following gentlemen and works:

Gen. Newton, U. S. A. Hell Gate Tunnel, L. I.
Messrs. Shant-Y. Hoosac Tunnel, Mass.
J. Dutton Steele. Nesquehoning Tunnel, Pa.
Sidney Dillon. Fourth Avenue Work, N. Y.
Col. Roebbling. East River Bridge Company, N. Y.

BROWN'S PATENT LAMP.

For Mills and Hydraulic Mining Claims.

One of these Lamps, when placed at a distance of 200 feet from the bank, will light up a bank surface 250 feet in length and 150 feet high, and to a much better advantage than any other light heretofore tried, and at an expense not to exceed five cents per hour. Lamps furnished at short notice.

[Letter of Recommendation.

Mr. C. B. Brown—Sir: Your Patent Lamp for lighting hydraulic mines, which you sold to me in December last, has given entire satisfaction, and far exceeds my expectations, and I think it the best and cheapest light ever used to light mining claims by night, and am satisfied that I have saved three hundred dollars by the use of it in the last mining season over pitch or any other light of the same brilliancy; and I will also say that if I could not get another lamp, five hundred dollars would not buy it. Yours,

W. D. APLIN.

Little York, Nov. 5, 1872.

Improved Forms of Rock Drill Points.

Written for MINING AND SCIENTIFIC PRESS by A. Blatchley.

There are few branches of mining which are not more indebted to modern science than Rock Drilling. The holes in the rock in mining and quarrying are beaten by blows of the hand in the same manner that the builders of the Pyramids wrought three or four or more thousand years ago. Whether they used the same form of drill point that we do, is uncertain, but it is probable that they did. We probably have better steel than they, but that is the only point whereby we surpass them. After the holes are drilled, we have in gunpowder and other explosives a means of rapidly tearing rock, which they did not possess.

In our cuts we have not shown the diamond drill point which is a section of a cylinder with diamonds set on its face, so that revolving the cylinder grinds out the hole. Or the diamonds are set in, in the end of a pipe, and when the pipe is revolved under heavy pressure, the diamonds wear away the rock and make a hole with a core in the center.

The use of diamonds is very limited and the supply small when compared to steel, and if all the rock work that is done by steel in one year were done by diamonds, all the known diamonds both carbons and brilliants would be required. The few required to supply rock drills have caused an advance in the price in the last three years of several hundred per cent., even the fabulous Arizona diamond yield of the fields failing to keep down the price.

In our engraving No. 1 represents what is called the diamond or lozenge-shaped point. It is the almost universal form used in drilling metals and is largely employed in rock drilling. Its sharp point is particularly useful in starting a hole in any given point; and in soft rock it is as efficient as one with a rounder form. No. 2 shows a form that is better adapted to harder rock, but No. 3 is the form most commonly prepared for the hardest rock, such as granite, mica slate, containing a large amount of siliceous matter, mica, etc., and amygdaloid, etc.

Figures 7 and 8 (the same figures though different views of the same drill) represent the cross and three-leaved point, and sometimes as many as seven leaves are used. Figure 7 shows an end view of the drill. The cross is generally adapted for machine drills and will sustain a heavier blow without breaking than a chisel point. All of these cut out the entire size of the hole as is shown at No. 6, which shows the form of the cuts at the bottom of the hole. No. 4 shows a double drill, (front and side view) two obisel points with the edges set parallel; 4 shows the manner in which it operates. It cuts around on the sides of the hole and the center flakes off, thus saving a large amount of cutting in drilling a hole.

This ingenious arrangement was invented by Charles Braid of Copperopolis, twelve or fourteen years ago. No. 5 represents a side and front view of a modification of this drill; the cutting edges are rounded so as to conform to this side of the hole as is shown at Fig. 5. This cuts a still smaller portion of rock as is shown at Fig. 5. This form of drill bores a hole with less expenditure of power than any other known form; the chips are larger, showing less cutting than when they are finer.

No. 6 represents a curious form which is sometimes used for leaving a center for holding a tool for chamfering out this pattern of a hole. One of the greatest improvements in blasting rocks, that has been made in later times, is the use of Giant Powder. By its great explosive force as much execution can be done with an inch and a quarter hole as by an inch and a half charged with ordinary gunpowder, reducing the work of drilling as eleven to seven, and one man with a hand hammer and a small drill can penetrate this rock nearly as fast as two men with a larger drill.

SOUTH AMERICAN MINES.—The yield of the silver mines at Corraoee near the boundary line between Chile and Bolivia, is about \$250,000 per month.

A New Style of Pavement.

The San Francisco Paving Company was incorporated in this city December 24th, 1872, the object being to produce a cobble pavement, which, while retaining the durability of the ancient cobble, presents a smooth and level surface for carriage traffic. This the above named company have undoubtedly accomplished, by the following method, viz: The cobbles, which are procured of as nearly a uniform size as possible, are fed with mathematical precision to a machine which cuts or clips one of the rounded ends of the stone, producing

AN IMPROVED PAVEMENT.

a level surface instead of a spherical one, which level surface the proprietors say they have every reason to believe will be permanent.

The advantages of this pavement over the cobble now in use is at once apparent by reference to the accompanying cut. In muddy weather no one with a humane heart can travel

New Zealand Mining Affairs.

The files of the papers which came to hand by the "Nevada," report considerable progress in mining affairs in New Zealand. The gold fields show many indications of paying as well as they formerly did and numbers of claims supposed to be worked out, are showing freely. Capital is being invested in machinery, tramways and other appliances of mining operations, and there seems to be a desire to put money in legitimate mining property rather than in shares.

A quicksilver mine at the Bay of Islands has

been leased from the natives for 99 years on consideration that the holders pay 25 per cent. of the profits from the sale of quicksilver to the natives. There are about 3,000 acres of mining ground.

The settlers there have had a little more enterprise in one respect than we have shown

DIFFERENT FORMS OF DRILL POINTS.

the streets of San Francisco without suffering a pang for the poor horse, who often drawing heavy loads, struggle and slide over the slippery cobble stones to the great detriment of their feet and limbs. Possessors of valuable horses, omnibus companies, and in fact all owners of equines will view the above method of paving with sincere favor, and it is to be hoped that our Board of Supervisors will carefully inspect these stones, before authorizing any more contracts. The officers of the company are Louis Duterhric, President; E. D. Sawyer, Treasurer and A. E. Ball Secretary.

The machine for clipping the stones is being built by Messrs. Martin & Co., and is now about completed.

MEXICAN MINES.—Rich gold and silver mines have recently been discovered in the Sierra de San Juan District of the State of Tamaulipas, Mexico. The latest reports from Tantima, Real del Norte, Gnanaxtato and Zacoatecas are favorable, and the production of silver the ensuing year is expected to be much greater than ever before. At the same time the high price of quicksilver will prevent the working of poor ores.

here in San Francisco. They have large and apparently inexhaustible deposits of titaniferous iron sand which is now being converted into iron and steel. An experiment was recently tried with 480 pounds of iron sand, which was placed in a furnace and left for two hours; at the end of that time the sand liquefied and the iron was pronounced to be of the first quality. It is understood that we have on this Coast extensive deposits of magnetic iron sand, but as scarce as iron is here we have made no effort as yet to utilize the product. The high price of fuel is probably the cause why nothing has been done with it here, but as far we know, no practical experiments have been made to determine its commercial value.

The New Zealand sand has previously been subjected to tests in England and is said to make first-rate iron. The large deposit in Canada has also been worked to some extent.

LARGE TUNNEL.—The Jamez River and Kanawha canal which is partially completed, is to pass under the Alleghany Mountains, through a tunnel eight miles in length. The work will cost about \$75,000,000 to complete.

Grindstones.

That a rapid advance has been made during the past few years in mechanic arts on the Pacific Coast, is evident from even a casual visit to the numerous and well appointed machine shops and mills in this city. Nevertheless there are specialties in mechanics in the Eastern States which have not as yet reached our comparatively distant shores, or which being known are not yet adopted. This is particularly noticeable in the varied and important uses to which grindstones are now put. Formerly their work was confined to the sharpening of tools only, but this is now but a small part of the uses to which they are put, as it has been found by experience that almost every kind of steel, iron (case hardened especially) and brass work used in finished machines can be ground better and cheaper than by filing. Almost every part of a locomotive engine is now finished on the grindstone, which leaves the metal in the best possible condition to receive the polish or paint in finishing. As will be seen by reference to our advertising columns, grindstones of special character are made for special trades, and those for grinding locomotive and machine work are particularly referred to.

Messrs. M. Baird & Co., of the Baldwin Works, Philadelphia, who are now making 40 locomotives a month, keep six grindstones of 4,000 pounds each running constantly on locomotive work alone, not only all the rough castings being ground, but 41 working parts of the engine are finished in this way, besides grinding off the faces of their axils, some of them weighing 700 pounds. The master machinists of nearly all the railway repair shops find it to their interest to keep at least one grindstone in use for this purpose.

Grindstones are also used in the East for finishing pulleys of all sizes. The pulley is caused to revolve against the stone which runs rapidly in an opposite direction, thus grinding down the face of the pulley very fast, and at less cost than by turning it in a lathe, besides leaving it perfectly true. It requires, however, a very peculiar kind of of grindstone for these purposes, the grit of which should be very sharp and firm, so as not to crush down with the necessary pressure, and yet not so hard as to glaze, and it requires considerable care and experience in making a proper selection.

Much more care than formerly is now exercised in the selection of suitable grits for sharpening machinists' tools, and it has been found that the first cost of a grindstone is of little consequence, provided it does its work quickly and well, a poor grindstone being dear at any price. The following hints have been found useful to those having charge of grindstones:

- 1st. Don't waste the stone by running it in water, but if so, don't allow it to stand in water when not in use, as this will cause a soft place.
- 2d. Wet the stone by dropping water on it from a pot suspended above the stone, and stop off the water when not in use.
- 3d. Don't allow the stone to get out of order, but keep it perfectly round by the use of a piece of gas pipe or a barker.
- 4th. Clean off all greasy tools before sharpening, as grease or oil destroys the grit.
- 5th. When you get a stone that suits your purpose, send a sample of the grit to the manufacturer to select by; a half ounce sample is enough and can be sent in a letter by mail.

WASTE.—In one department of the Vienna Exhibition there are to be shown products now obtained from substances which at the time of the London Exhibition of 1851 were wasted.

CORRESPONDENCE.

White Pine Mines.

(Written for the MINING AND SCIENTIFIC PRESS.)

EDITORS PRESS:—The total destruction of the International mill in August last, was a serious, though temporary blow to this mining interest of this district. Fortunately it occurred at a time when the company's mines were in a better condition, and yielding richer ore than at any time during the past two years; and could suitable milling facilities have been procured, work in the mines would have progressed as usual. As it was, no suitable mill could be procured and the company was obliged to suspend operations in their mines for a time, thereby throwing 200 men out of employment just at the most inclement season of the year. And to make matters worse all the large companies in the district followed suit by reducing their working forces to the lowest possible standards, retaining only a prospecting force or from 4 to 8 men. So that on the commencement of the present year there was not over 50 miners employed in the whole district.

At the present time, however, the prospect has somewhat improved with fair

Indications of a Prosperous Season

The coming summer. The Eberhardt and Aurora Co. have secured a lease of the Stanford mill for six months, and have resumed work in their mines with the usual force. The mill is situated close to the tramway so that they can deliver their ore at the mill regardless of the severe storms and drifting snows which have rendered the roads impassable ever since the new year. Several of the mines in which work has been continued have improved greatly since the commencement of the year, both in the quantity and quality of the ore exposed. Some preparatory work is being done in the 'Base Range' with a view to making another effort during the coming summer to inaugurate successful smelting.

The New Railroad.

But most important to the mining interest of this community is the promised early completion of the E. N. N. G. R. R. Cheap and quick transportation is the great desideratum for the whole of the Eastern Nevada mining region. Its influence would be felt in the stimulation of all kinds of mining to increased activity, but more particularly would those districts be benefited whose resources consist wholly or in part of the so-called base ores, such as the extensive 'Base Range' of this district, all of Robinson with its monster deposits, and a host of other localities. Cheap transportation, by opening a way to a market for the produce of the inexhaustible stores of argentiferous lead ore now lying idle, would double the bullion product of the State in a very few years.

The Bullion Product

Of the district owing to the destruction of the International mill and other causes has fallen \$500,000 short of the usual yield, reaching for the year only the meagre sum of \$860,541. The whole amount of free milling ore produced in the district since its discovery, is 161,271 tons, which gave a gross bullion yield of \$7,864,632 or about \$43 per ton. To this may be added 10,442 tons of smelting ore that sold on the dump at an average price of \$14.50 per ton, and produced lead bullion worth \$443,685, making the whole bullion product of the district to date \$8,308,377, a fair showing for a district that has not a single mine opened to a depth of 200 feet from the surface.

The Mines.

The Ward Beecher and Aurora North are the property of the Eberhardt and Aurora Con. Co. They have been worked extensively since the commencement of 1870, and have yielded in that time about \$1,500,000. Their present appearance is such as to warrant the expectation of an increased yield for some time to come. The old ore deposits still continue to yield about fifty tons of ore per day; with no evidence of being soon exhausted. Since the resumption of work, two new deposits of excellent ore have been developed at a greater depth than any heretofore found on Treasure Hill. The first of these was found under the old chamber south of the engine shaft, and is probably a continuation of the ore worked above. It is to all appearance extensive, and as rich as any heretofore found in the mine. The other end most important deposit was found in the south part of the mine, near the South Aurora line. The upper tunnel of the South Aurora has been extended north, under the old chambers in the North Aurora, without finding any indications that the surface deposits continued in depth. Since resuming work a winze has been sunk from the end of this tunnel, and at a depth of twenty feet an entirely new deposit of ore was found. The winze is already in eight feet of the richest kind of chloride ore, without finding bottom. Both of these deposits are over two hundred feet from the surface. This Company has been singularly fortunate in always finding new deposits before the old ones are exhausted; it may be attributed to blind luck, but perhaps more reasonably to skill acquired by long experience, backed by plenty of cash for dead work.

The Edgar Mine.

This mine is a part of Ward Beecher Consolidated, and is situated next north of the last-named. It is on the line of the main north-and-south ore channel, and from every indication all it requires to make it as good a piece of property as any in the district, is good management, backed by a little more vigorous prospecting than it has heretofore had. A large deposit of excellent milling ore has lately been discovered 160 feet from the surface, and thirty feet below the old works.

The Original Hidden Treasure

Was the first free metal mine found on Treasure Hill. It is apparently situated to the east of the main ore channel, but still contained large deposits of good ore, and was for a long time a favorite with local stock speculators; but it appears to have fallen into disfavor lately, and not without good cause. The surface deposits have been completely worked out, and its future depends altogether on what may be found in the deep workings. The prospects are anything but encouraging, still the Wheeler tunnel may find something valuable, should it be continued far enough west to strike the main ore channel.

The Mammoth and Noonday each work a small force, and take out some good ore.

Treasure City, Feb. 10th, 1873. A. J. B.

Resources of Utah—Some of the Principal Mines.—Continued.

The Mountain Lion Mine.

Situated on the summit of Lion Hill, East Cañon, Ophir District, discovered in the fall of 1870. The principal owners is Mr. Ormus Bates, of Ophir.

This mine has been opened more to prove its extent than for the extraction of ore, while much dead work has been done on account of tracing out "jumpers," who took up locations around when the value of the property was established. Notwithstanding the above disadvantage, large open cuts, shafts, dips, etc. have been made, and immense bodies of ore exposed, extracted and sold; and the fact has been established that this mine has a perfect and inconvertible title, and will embrace, when further developments are made, several mines in the vicinity which are located on the course of its vein. It can already trace the Blue Wing, Webster, Defence, Sunnyside and others upon the same vein of mineral. In support of the value of the property, we are credibly informed that one of the original locators sold to Mr. Ormus Bates 200 feet in the fall of 1871 for the sum of \$20,000 gold coin. Also, that in the month of April, 1871, Mr. Q. A. McConnell, then of the U. M. & S. Co., bought and shipped 20 tons of ore from the owners of this mine to Swansea, England, for which the owners received \$4,000 net. This was at that time considered a fair average of the value of the ore. The average width of the vein is estimated at about six feet, and the average assay value is about \$150 per ton; also assays were given as high as \$4,000 to the ton. Numerous pockets of horn-silver have been met with in the course of developing the mine. It is considered that, so far as worked, the mine has paid for itself. The general character of the ore is carbonates and sulphurets, with a very small percentage of lead.

The Miner's Delight, or the Blue Monster Consolidation.

Located on Ophir Hill, East Cañon, consists of the following series of mines, Blue Monster, (the oldest title,) Velocipede Nos. 1 and 2, Silver Shield and Pocahontas. The Blue Monster was discovered July 4th, 1870, and the Miner's Delight July 28th, 1870, and the others at subsequent dates. The mines are owned and are being worked by an English Company.

By the statement of the resident manager, S. Blackwell, Esq., dated March 1872, \$1,000,000 worth of ore was then in sight. The assay value of the ore was \$116 in silver, 52 per cent. of lead and \$5 of gold per ton. The character of the ore is carbonated. It can be smelted without fluxes and worked with little or no blasting. While developing the Silver Shield and Velocipede, fifteen hundred tons were extracted and sold, which assayed \$50 in silver and 45 per cent. lead to the ton. There are five tunnels, five shafts, and numerous drifts, which, passing as they do sectionally and longitudinally through the vein, would, if in a continuous line, extend over ten thousand linear feet. There is on the dumps of the different mines about four thousand tons of ore, which is being held until the erection of patent machinery designed and experimented upon by Capt. Selwyn, R. N. It is expected that in the spring, active operations will commence to develop this valuable property, as the obstacles that have heretofore impeded the work are in a fair way to be removed.

The Panaca Mine

Is situated in Mineral Fork, Big Cottonwood Mining District, and is at present receiving much attention. It is on the ridge or divide between Bear and Mineral Fork gulches, and is opened by a shaft on the ridge and a tunnel on either side of the mountain, which exposes the vein and shows a sectional width of high grade mineral four feet in thickness. The vein is

traceable on the surface up and down the hill for a distance of fifteen hundred feet, which proves it to be a fissure vein. By triangular calculations from workings on the vein, where exposed, it is estimated that \$300,000 of ore is ready for immediate extraction. The owners are perfecting arrangements for active operations in the spring.

The Chicago Mine

Is situated on Hidden Treasure Hill, Dry Cañon, Ophir District, at an altitude of nine thousand feet above the level of this sea.

Work on this mine commenced in the summer of 1871. The mine is owned by Wm. S. Godbe, Esq., of Salt Lake City. The extent of the claim is 2,000 linear feet. The main incline is down 250 feet. At the depth of 240 feet two drifts, 50 feet in length, have been run at right angles with the incline. The pitch of the incline is about 40 degrees in a northwesterly direction. Incline No. 2 is 80 feet deep, having an average angle of from 40 degrees to 45 degrees, and is connected with the main incline of that depth. Incline No. 3 is 30 to 35 feet deep. It has the same angles as No. 2, and connects with it at the above named depth. Incline No. 4, or "Rembler," is between 40 and 45 feet deep, but is not yet connected with the ore. All these developments are westerly of the main incline. Incline No. 1 easterly is about 20 feet deep. Incline No. 2 easterly is down about the same depth. Some 500 tons of ore were taken out of the mine during the year 1872. The average assay value is 50 oz. in silver and 40 per cent. lead. The formation is limestone in strata, between which the vein occurs. The character of ore is carbonates of lead mixed with galena. The vein averages from 5 to 25 feet in thickness. The works and buildings connected with the mine are very substantial, extensive and well arranged for doing a large business. They consist of a large dump house, the wall of which is of dry rock 75 ft. long by 25 ft. high, affording dump room of the capacity of 75x50 feet. The whim and blacksmith's shop are under cover at the mouth of incline No. 1. There is a stone powder house, log stable with six stalls, an office, store-room, cook house and large log house for the accommodation of 30 workmen.

This chute is 130 feet long, 18 inches high and two feet wide, made of two-inch lumber and lined with heavy sheet iron. The ore is passed from the mine down the chute into a log ore house capable of holding two hundred tons. With the present appliances thirty tons of ore can be taken out of the mine in every twenty-four hours.

A roadway a quarter of a mile in length connects the mine with the Fourth of July mine tramway.

The Kelsey Tunnel

Mining Company's locations, owned by Kelsey, Shearman and some New York capitalists, in Bingham Cañon, are situated on the same ridge as the great Winnamuck Mine, and only 2,800 feet distant therefrom. The claim comprises a tunnel site and ten valuable mineral veins, aggregating over twenty thousand feet of mining ground. The Kelsey Tunnel has been run into the base of this ridge for the distance of three hundred and thirty feet, cutting across two very large veins of mineral. The vein upon which the Winnamuck Mine is located undoubtedly runs through the ridge penetrated by this tunnel, and it is believed by the proprietors that they will have but little further to run their tunnel, before they will tap that great mineral vein. The Bingham railroad runs within two hundred feet of the face of this tunnel.

The New York Tunnel,

Owned by Messrs. Kelsey & Shearman, will tap a very large belt of well-known mineral veins at great depths, and furnish a constant drainage to a large amount of very valuable mining ground. The mouth of the tunnel is within five hundred yards of the line of the railroad in Bingham Cañon, and is of easy access by a good road already made.

Vespasian Hill.

Messrs. Kelsey & Shearman also own sixteen parallel veins on this hill, at the head of Markham's Fork of Bingham Cañon, distant one and one-half miles from the line of the railroad. This group of mines aggregate nearly forty thousand feet of mining ground. The Vespasian mine—the middle vein of the group—has been worked by an incline shaft to the depth of 308 feet, developing a fine body of mineral that ranges in assay value from \$14 to over \$1,600 per ton in silver, and from ten per cent. to seventy per cent. in lead. This mineral vein has been opened by shafts of limited depth for a distance of 1,500 feet along the surface, showing everywhere an even out-crop of over three feet in thickness. About one hundred tons of mineral is on the dump of this mine that will average near one hundred dollars per ton in silver and twenty per cent. in lead.

The Agnes Mine

Owned by Mr. Kelsey, Shearman, Godby & Chelerson, is a very fine prospect. A shaft fifteen feet in depth has been sunk on the vein—showing a three feet crevice—the half of which is filled with ore averaging 33 per cent. in lead and \$265 per ton in silver, the balance of the vein being filled with quartz, assaying \$12.50 per ton in silver. This valuable prospect is situated near the divide between Little Cottonwood fork of Bingham Cañon and the head of Pine Canon, Tooele county, and accessible by wagon road. Messrs. Kelsey & Shearman, also own many other excellent prospects, chief of which, are the Blackbad and James in Carr

fork, the Red Cloud, in the vicinity of Yoeemits mine, the Scarborough, near Black Jack Gulch, the C. A. Dene, near the Agnes, the Herry Clews Prntice, in Freeman's Gulch, and the Ella et the head of the Merken—all of which yield very fine surface assays.—Salt Lake Tribune.

The Mineral Belt of Colorado.

It can be stated without fear of contradiction now, that explorations have been made very generally along the main range, its spurs and foot-hills on either side in Colorado, that the mineral belt of the Territory extends from its northern to its southern boundaries over an extent of Territory at least fifty miles in width. To arrive at some idea of the vast area embraced within these limits, we must consider that the Main Range in Colorado owing to its tortuous course is at least five hundred miles in length. This with its breadth of fifty miles shows the mineral belt in Colorado to contain 25,000 square miles, or 16,000,000 square acres. And already prospectors have explored this immense tract sufficiently to fully demonstrate the existence of the precious metals through its entire extent. Of course at this early day in the history of mining industries in the Territory, there has not been actual operations which have fully proven the continuity of ore deposits from the discoveries at the head of North Park, to these on the Rio Grande on our southern boundaries, still wherever explorations have been made in the area above mentioned, minerals and the precious metals have been discovered, and in all instances bearing features and characteristics common to these in fully developed districts.

The silver-bearing deposits of this belt are mainly in the Main Range and its spurs, in the Granite formations, and the ores of these are as a rule, sulphurets of silver, lead, zinc, copper and iron, with sulphurets and sulphates of nearly every known metal and mineral.

The gold deposits, both superficial and enclosed of this belt are chiefly in the foot-hills, on either side of the range, and in the valleys and parks that skirt the innumerable streams that break through these at various points. In these superficial deposits the gold exists in its native state amidst the drift material peculiar to these valleys, and in the bed rock which underlies this "wash" from the mountains above. The enclosed deposits are mainly in the gneiss and gneissoid formations, in fissure veins, or lodes, and the gold in these is in mechanical combinations with sulphurets of copper, iron, lead, zinc, antimony, arsenic, and various other minerals and metals, and perhaps, occasionally, in chemical combination with sulphur as a sulphide of gold.

The principal districts on the Eastern slope where the silver mines of this grand belt have already been developed to any considerable extent, commencing at the North, are Grand Island district in Boulder county, the home of the great Caribou mine, the mining districts surrounding Idaho, Georgetown, Fairplay, and the comparatively unknown San Juan region; and on the Western declivity, the districts around Montezuma and St. Johns. Between the developed portions of these geographical divisions thus hastily considered, numerous discoveries of lodes have been made, and at many points mining operations are now successfully prosecuted.

The fully explored "gold belt" commences on the North on the eastern slope, with Word and Gold Hill districts, in Boulder county, and continues on southward through Gilpin county, and southward and westward to the western rim of South Park, and still westward and southward around the headwaters of the Arkansas, and southward to the San Juan mountains in Conejos county, on the southern boundary of the Territory. On the western declivity of the range, the gold belt extends from Middle Park southward, through the districts around Breckenridge and the headwaters of Ten Mile and the Blue River. This vast area, rich in mineral and metallic wealth is without parallel in the world, and is destined to yield untold treasure to its fortunate possessors, a great nation and the pioneers of this new and wonderful country—Colorado.—Georgetown Miner.

COAL IN CHINA.—According to Baron Richthofen and others, the Chinese coal-fields cover an area of upwards of 400,000 square miles; 12,000 miles of coal have sufficed to make Great Britain the greatest workshop of the world. In the province of Hunan, a coal-field extends over an area of 21,700 square miles. There are two perfectly distinct coal beds in Hunan, one bearing bituminous and the other anthracite; the latter being most conveniently situated with regard to conveyance by water, easily mined, and covering an area equal to that of the anthracite coal-fields of Pennsylvania. In quality this coal will compare favorably with the best kinds of anthracite known. The coal area of the province of Shansi is of the enormous extent of 30,000 square miles. This is capable of supplying the whole world, as its present rate of consumption for thousands of years, and has unrivalled facilities for mining. The beds are from twelve to thirty feet in thickness, while the system of coal-bearing strata in this province is about 500 feet in thickness, and contains, beside, an inexhaustible supply of iron ore. Ping-ting chau is conspicuous for an extraordinary and exceptional favorable juxtaposition of coal and iron.

SCIENTIFIC PROGRESS.

An Electrical Tower.

Below will be found something in addition to what we gave last week under the head of a "Novelty in Telegraphing," which we copy from the *Scientific American*:

Mr. William H. Ward, of Anburn, N. Y., has suggested an electrical tower for accumulating natural electricity for telegraphic purposes. The structure which is to be placed on high mountain peaks or other elevated stations is to be made in three sections. The lower portion is a mere shell containing a door. Above this and insulated from it by a diaphragm is the middle part in which are openings or windows having slats pivoted in them, so that, by means of raising or lowering rods suitably connected to such shutters, the openings may be shut or opened. A projecting rod extends over the windows, serving to protect them from the weather and also for receiving the aerial electricity which may be drawn from it by wires for land line purposes. Above this roof is another insulating diaphragm. The highest portion of the tower is surmounted by a bent ventilating tube and vane, so arranged and connected with the rods acting on the shutters that the revolution of the vane by the wind will open the windward and close the leeward slats. The wind therefore assists in driving an aerial current of electricity into the insulated middle portion of the tower, which current passes upward through the upper portion of the tower and out through the ventilator, thus forming a draft by means of which the electrical current is forced out at the vane. Insulated wires leading from the top portion of the tower allow a supply of electricity to be drawn therefrom.

By the use of the aerial electricity which surrounds the earth in the upper strata of the atmosphere, the inventor considers that artificial batteries may be entirely dispensed with, and a circuit formed merely by connecting the aerial current with the earth current. For instance, to bring Buenos Ayres, in South America, in direct connection with New York the following plan would be pursued: one electrical tower is erected on Pike's Peak or any other suitable high mountain in North America, and another similar tower on some suitable peak of the Andes in South America. The former would, by means of land lines, be connected directly with Denver, which place is again connected with all the prominent cities of the States. In a similar manner the southern tower is connected by land lines with prominent cities via Quito. New York telegraphs to the tower on Pike's Peak, and the operator having connected the land line with the aerial current, the signals are transmitted through the aerial current to the town in South America, and thence—the land lines being suitably connected—to Quito and Buenos Ayres.

Interesting Chemical Experiment.

An experiment involving a molecular change in the condition of an element, can be performed as follows:—Let a copper and platinum strip form respectively the negative and positive terminals of a galvanic circuit; immerse these in a hydrochloric solution of chloride of antimony. The result of the galvanic action will be the precipitation of the antimony in form of a fine impalpable powder upon the surface of the copper, from which, when enough has accumulated, it may be readily removed by bending the copper strip back and forth. The metal thus obtained, if placed in a mortar, and vigorously triturated in with the pestle, will detonate with some violence, the explosions being at the same time accompanied with the evolution of light and heat. This curious phenomenon appears to be purely the result of a molecular change, induced in the metal by the mechanical force employed; the consequence being the conversion of the amorphous powder to a crystalline condition. It would be of some interest to note whether the same result would follow the application of heat to the powder, since, from the announcement of Bunsen, made some years ago, the metals rhodium and iridium, when deposited from solutions of their salts in an analogous manner, manifest this property in an extraordinary degree; so much so, indeed, that the scientific world came very near losing the invaluable services of its illustrious discoverer in consequence of a severe accident which befel him from this very unexpected source. It would be a matter of no little interest to trace the analogy here indicated, to one of positive identity in kind, by investigating the behavior of such precipitated antimony when heated, as was the case with the platinum metals experimented upon by Bunsen.

LUMINOUS TUBES.—A NEW EXPERIMENT.—If fifteen to twenty grammes of granulated silver are introduced together with thirty to forty grammes of bisulphide of carbon into a hard white glass tube, and hermetically sealed, then, upon gently warming and then shaking in the dark, sparks will be observed in the tube, which by continued shaking may be rendered quite luminous. Pouring water on the tube causes the luminosity to disappear, but, upon shaking, it reappears again.

Fires and the Atmosphere.

The question why fires at certain times spread so much more rapidly, and are so much more difficult to check, than at others, possesses a very high degree of importance and interest. After all the reasons that can be given for the spread of most of our great fires, nearly or quite all the causes assigned, both by practical and scientific men, could generally be found to exist in cases where the conflagration was comparatively slight, and where the means of extinguishing it proved no less effective than usual.

Every one who regularly attends to an ordinary grate or stove, has frequent occasion to observe that a fire, which burns brightly at certain times with a certain draught, will often require, at other times, a much greater draught to keep it from going out. In some cases this is readily understood; but in many instances it is in a very great degree owing to causes which neither science nor practical observation knows anything about.

The simple fact in regard to the whole matter is, that the different states of the earth's atmosphere are a subject concerning which, like a great many other things, science is able to tell much less than scientific men are generally willing to acknowledge. There are certain philosophic truths, indeed, in regard to the atmosphere, which are well ascertained, and respecting which no one capable of understanding them can have any doubt. But there are others in reference to which we are as ignorant as the ancient Romans. There are very many phenomena connected with the subject of the air we breathe, for which science utterly fails to account, and among these the numerous phenomena produced by the action of fire, occupy no unimportant position.

There is sometimes, in case of a very destructive conflagration, a kind of criticism heard, in respect to alleged want of efficiency in the firemen, which is unreasonable, as the blame often attached to a doctor when a patient dies of a disease from which an individual has, under the care of another physician, recovered. The cases of the two patients—although, so far as could be seen, exactly alike—may have been, in reality, entirely different. So with fires. The skill and energy which will effectually check one, will not always prevent the spread of another, although the circumstances may be, apparently the same.—*N. Y. Times*.

BIELA'S COMET.—Astronomers do not universally indorse the idea that the object discovered by Mr. Pogson, on the 2d of December, was without doubt the lost comet of Biela. All that is certain is that Mr. Pogson turned his telescope on the track of the retreating meteors of November 27th, and saw an object of cometary appearance. If really Biela's comet, something very extraordinary must have happened to that body, which, according to the very accurate calculations of its path, would have been in perihelion on the 14th of October, whereas the group of meteors which produced the shower seen here on the 27th of November, did not arrive at its nearest distance from the sun until the 25th of December. The earth crossed the orbit of that comet, with which the meteors appear to have so remarkable a connection, on November 27th, but the comet itself was far away, unless some catastrophe had occurred to it since last seen, concerning which speculation is quite at fault. It is more likely that what Mr. Pogson saw was another concentration of cometary matter in the orbit of Biela.—*London Athenaeum*.

THE ELECTRIC DEPOSIT OF COPPER.—It is a recent French discovery, that adding a minute quantity of gelatine to a solution of sulphate of copper, prevents the brittleness which copper is said to have that has been deposited by the action of the galvanic battery. The philosophy of this result is unknown. The softness and malleability of copper deposited from a solution of a copper salt by electrolysis is increased by increasing the conductivity of the solution. This acid added to the bath until it has reached the point when the hydrogen gas is about to be given off, will hasten the decomposition, and the copper obtained will be soft and pliable. But what gelatine does to produce an effect, or rather why, we do not understand, any more than we understand why a little sulphuret of carbon added to the solution of a bath for electro-deposition should have the alleged effect of causing the deposit to be so bright as to need no burnishing afterwards.

INFLUENCE OF PRESSURE ON THE SPECTRA OF GASES, AND ON THE ELECTRIC CURRENT.—A foreign contemporary publishes the following information as an observation of M. Cailletet: When a spark from an induction coil is passed through a tube containing a gas under ordinary pressure, the light is feeble and presents in the spectroscopic very indistinct bands. But if the pressure be slowly increased, the bands will become brighter and broader, producing in the end a continuous spectrum. Upon reaching a pressure of two hundred atmospheres the electric current ceases to pass.

CONSERVATION OF FORCE.—Dip the hand in a finger-glass until the temperature of the water therein is raised one degree. An amount of energy is withdrawn from the hand sufficient to project that water to a height of 772 feet above the earth's surface.

A Fatal Flaw in the Darwinian Theory.

Muller recently delivered a lecture before the Liverpool Literary and Philosophical Society on the phase of Mr. Darwin's theory which deals with the possibility of animals acquiring the faculty of articulate speech. Mr. M. maintained that the true barrier between man and beast was language. He gave various illustrations of the essential difference between the expressions of emotions—the language of beasts, and the expressions of ideas or abstract conceptions—the language of man, and argued at length on the impossibility of mere emotional signs or sounds being developed into articulate speech. He ridiculed the idea of the possibility of a gradation from the neigh of a horse to the poetry of Goethe! Man and animals possess emotional language in common, because man is an animal; but brute animals do not possess rational language, because they are not men.

Rational language is traced back to roots, and every root is the sign of an abstract idea, and not the demonstration of an emotion. Mr. Darwin has seen the importance of overthrowing this bar to the maintenance of his theory, and has assumed to find savage languages, which contain no abstract terms; the fact that such have been found is denied. The lecturer holds that until Darwin finds a language containing no terms expressive of the abstract ideas of father, mother, brother, etc. he fails to maintain his position.

MECHANICAL PROGRESS.

The Canal Navigation Award.

The one hundred thousand dollar reward offered in 1871, by the Legislature of New York, to the introducer to the inventor of a plan for a more economical plan for the navigation of the Erie canal, has brought out numerous inventions and plans to that end. Not less than sixteen inventors entered upon the contest, and made actual experiments on the line of the canal—one, however, inventing the use of an engine on the tow path as a traction engine, was ruled out, as not coming within the limits of competition. Another, consisting of a steam rope towage, by means of a wire rope laid along the bottom of the canal, after the plan used to some extent in Europe, was also ruled out. Ten of the devices appear to have given results more or less satisfactory. Four were not satisfactory.

The *Scientific American* says that in respect to nearly all the exhibits they have demonstrated the fact that canal boats may be successfully operated by steam power; but that none have fully and satisfactorily fulfilled the intent and conditions involved in the award.

The next inquiry is whether any of the exhibits are likely, on further trial and such improvements as experience may suggest, to accomplish the ends required. The general impression is favorable for such a result. It was demonstrated by a majority of the boats tried that the cost of transportation by steam may be done at about one-third the expense of horse-towage.

Capt. Goodwin's plan of a train of boats, drawn by a single steamer, appears to be the most promising, and the Captain is very confident that if more time is given him to make modifications in his plans, he will be able to solve the problem of canal navigation in a manner entirely satisfactory. Other inventors, also, appear to feel hopeful of their individual plans, and nearly all have joined in a memorial to the Legislature asking for an extension of the time, which, under the original award, expired with the close of navigation last fall. The subject is of so much importance to the State that it is thought the Legislature will grant the extension asked for.

STEEL RAILS.—It is said that the demand for steel rails during the past year has been so great that they can hardly be obtained at any price; the supply is limited from the lack of ore free from sulphur and phosphorus, and recourse has been had to extensive mines in Spain. It is hoped that America will supply herself with steel rails, and import only those of iron required for new lines or light traffic. There is a scarcity of suitable ore for the Bessemer process throughout Europe, except in Sweden, where the recently discovered coal will render the ores more available.

NEW PROCESS FOR PLATING.—A Hartford, (Conn.) man has invented a new process of plating iron or any composition metal either with gold, silver or nickel, the plating being so driven into the surface that it becomes a part of the metal itself. Experiments have been made on boiler iron at Colt's with perfect success, and the government is going to test the merits of the invention.

Value and Utilization of Water Power.

During a late speech at Lonsville, General Butler said, on the subject of the utilization of water privileges for manufacturing purposes: "There is one bond-servant that we have in Massachusetts which you have not yet captured and made work for you. You have a river 500 miles in length with falls of 26 feet. We have a river in Massachusetts—the Merrimack—of only 90 miles in length, and we have captured it, and made it do the work of 65,000 horses. In adding to your industry that power—you have it right here—you will find that you are using a power which will increase your facilities with the least cost. It is the secret of Massachusetts' prosperity—a state with a sterile, rocky soil, and eight months of winter."

We never look at the rivers of California, without wondering that so little is done to utilize them, either in the way of irrigation, or in harnessing them to machinery. The remarks quoted above are quite as applicable to this State as to Kentucky. At a single locality on the Merrimack river at Lowell—10,000 horse power has been utilized, which has been the means of collecting a population of 40,000, producing an annual value in manufactures of \$24,000,000. Fall River has a population of 23,000, and a valuation of \$17,000,000. Lawrence, with a power nearly equal to Lowell's, has already a population of 30,000. It has been laid down as a safe proposition that a population of 1,000 may be looked for to each 166 horse-power employed in textile or equivalent manufactures, whether that power be derived from water or steam.

Moreover it is not absolutely necessary that our rivers should plow over dams or down rapids to utilize their power, to at least a moderate extent.

At any point in a stream of reasonable depth, large paddle-wheels may be attached to an anchored boat, or to a staging built across or out into the stream, which may be turned by the water that flows incessantly beneath, and which would thus catch a vast deal of power, which, for the want of such similar contrivance, we now extract from coal at a cost of from \$10 to \$15 per ton. Such wheels are largely employed by our California miners for pumping purposes; but we have no recollection of ever seeing such wheels employed for any other purpose, either in California or the Atlantic States.

At Mainz, on the Rhine, all the grain is ground by mills located on boats, like those above described, notwithstanding the inconvenience of their presence to the crowded commerce of the river. The barges are located in a line straight out from the shore, one beyond another, and perhaps a dozen in number. In the dearth of coal prevalent in England, ingenuity is racked to find new sources of power, and a Mr. Bramwell proposes to erect dams across narrow inlets of the sea, and when the tide comes in to shut it in and make it work a turbine wheel and pump water into a system of accumulators, when it would be transmitted to neighboring manufacturing districts. This is possible from the fact that a very small pipe, if strong enough, will transmit hydrostatic pressure to any distance or depth, as perfectly as though it were a canal.

Electricity vs. Boiler Scale.

There is good reason to believe that electricity will yet be made to prevent, at least in a great measure, that great annoyance to engineers—the formation of scale in boilers. The theory of this preventive is given as follows:

That as an electrical current will decompose a chemical compound in the Chemist's Laboratory, it can be made to do the same work in the steam boiler, the sugar pan, the salt kettle, and any other vessel upon which mineral or earthy salts are deposited. The electric current destroys the affinities by which the salts are held together and adhere to the boiler metal. This result is accomplished by placing the boiler in circuit with a galvanic battery, which is removed from time to time, like batteries used in the telegraphic service. The result is the incrustation does not form under galvanic influence, the substances that otherwise would go to form scale remaining in a soft decomposed state, which can be ejected through the blow off pipe like any other soft sediment. This method of preserving boilers from the evils of incrustation has been in use in some parts of the country for five or six years, and is beginning to attract considerable attention because of its novelty, and the new field of scientific research which this solution of a difficult problem has brought about.

TINNING CAST IRON.—A correspondent of the *Scientific American*, in reply to another who asks for a method of tinning cast iron, says: I used to tin boxes by heating them, then using a flux of alcohol or salt of ammonia, and tinning with a common soldering tool or a copper wire swab, with melted solder. They were cast iron boxes for steam engines and other purposes.

Another reply to the same query is as follows: A process for tinning common cast iron is one of the things that is yet to be found out. Any person having a process to tin gray iron and to give it a finish equal to what is known to the trade as C plate or even to give it a smooth coat of tin, would have too good a thing to let lie round loose.

MINING SUMMARY.

The following is mainly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR COUNTY.

HOOPER.—*Amador Dispatch*, Feb. 22: We are informed that they have struck some very rich rock in this mine at Plymouth.

MORNING STAR.—Hooper's works have been erected at this mine, and the work of hoisting rock, will commence next week.

PLACER MINE.—*Amador Ledger*, Feb. 22: We are pleased to learn that our placer miners are all in high spirits over the prospects of having a good supply of water, and as soon as the storm is fairly over we expect to hear of some very flattering clean-ups. There is much ground in this vicinity that would pay good wages if water could be had to work it. In and around Volcano there are some rich mines now being worked.

CALAVERAS COUNTY.

GRIN.—*Calaveras Chronicle*, Feb. 22: The progress of operations continues highly satisfactory. The yield last week was greater than ever before, averaging about \$1,500 per day. The recent storms have not interfered with the working of the mine in the least, causing no perceptible increase of water in the shaft. We learn that the work of sinking the south shaft 100 ft. deeper—making 700 in all—will be commenced shortly.

HUMSON.—We learn that rapid progress is being made in sinking the shaft on this mine. The contractors expect to have 50 ft. of the 100 to be sunk, completed by the first of March. The ledge is looking first-rate and the prospects of the mine are flattering. The shaft will be 230 ft. in depth when the present contract is finished.

COMMENCED WORK.—Messrs. Schrack & Robinson, who for several months past have been engaged in opening a hydraulic near the Mokelumne Station road, about a mile this side of Messengers', are just commencing operations. They were compelled to dig a ditch several miles in length to conduct water to their claim, and the performance of a great deal of other labor was necessary in getting ready for washing. The hydraulic has a pressure of about 150 ft. we believe, the water being conducted through a 7-inch iron pipe.

EL DORADO.

MINING DEVELOPMENTS.—*Placerville Democrat*, Feb. 22: We are informed that new developments of rich deposits have recently been made in Jones' Hill, above Georgetown, and also in this sterling old mining camp of Mammoth Hill. The abundant water supply secured by the late enlargement of the ditch is greatly stimulating the mining industry in that portion of our country.

POCAHONTAS.—*Folsom Telegraph*, Feb. 22: This mine situated near Shingle Springs, is proving to be a very rich mine. A few days since we were shown some exceedingly rich rock struck lately at the lowest depth in their main shaft. The mines in El Dorado county, wherever a sufficient depth has been attained, are proving to be as rich as those of Amador or Nevada counties. The fact is the same ledge extends through all of the above named counties.

KERN COUNTY.

BRIGHT STAR.—*Havilah Miner*, Feb. 22: The proprietors of this mine have discovered and opened a rich chimney of quartz, which measures 6 ft. from wall to wall. It prospects magnificently, averaging \$41 to the ton. It was struck after running through a thick seam of clay. They now contemplate opening the mine along the entire ledge, a distance of several thousand feet.

ST. JOHN.—This Co. have their shaft sunk 600 ft., with no diminution in its richness or width of chimney. The stamps are kept in constant operation.

McKEANEY.—These mines are in a most encouraging condition. Rich rock is now being extracted. A run will be made as soon as the new machinery arrives from below.

VENUS.—One of a very valuable character is being taken from this mine.

ST. PAUL.—A road has been completed to this new mine, preparatory to making a run.

SOMER.—This mine is turning out a large amount of bullion. This mine shows a finely developed ledge of immense richness. It can be favorably compared with any mine on the coast. Report says that the company contemplate erecting a 40-stamp mill, which, in addition to the old one will make a crushing power of 56 stamps.

FRANK STAPLES & Co. have partly constructed a road to their new mine. An 8-stamp mill will be put up in Bull Run Creek, a few yards distant from the mine, next month.

NEVADA COUNTY.

INAR.—*Grass Valley Union*, Feb. 22: This mine seems to have taken the hit in its teeth and is running away. After a 3-days run, this week, the amalgamators of the mill were skimmed off and the skimming gave \$12,000 worth of gold.

PLACER COUNTY.

SNOWEN.—*Placer Argus*, Feb. 22: From a correspondent at Michigan Bluff, we learn that the mines in that section of the county have not been able to work their claims for the past two weeks on account of the great quantity of snow. They have had no water in the ditches during that time. The prospects for an abundant

supply of water was never more flattering for mining operations in the spring.

PLUMAS COUNTY.

IAON MINE SOLN.—*Plumas National*, Feb. 15: It is reported that the iron mine near Mohawk Valley has been sold to a party of heavy capitalists and it is thought that some very extensive operations will be commenced in the spring towards opening and developing this vast deposit of iron ore. That highly renowned scientific explorer, Clarence King, pronounced this mine the finest body of ore west of the Rocky mountains.

SHARP LAKE.—*Cor. same*, Feb. 20: Metcalf & Co. have their new reservoir and ditches in first-class order, claims about ready to operate on with a Little Giant, etc. Smith Bro. & Co. are following the even tenor of their way and doing well, plenty of gravel, and water to wash it up. The Forest Hill bedrock tunnel is still being prosecuted, and the company expect ere long to strike the gravel and pay grit. The Mendoza Hill is lying idle for lack of water. The Wapponese Creek boys are all doing well. Old Bean Hill has turned out well; took out over \$2,000 in 12 days' run.

SAN DIEGO COUNTY.

STONEWALL.—*San Diego World*, Feb. 15: This mine continues 12 ft. while on the 140 ft. level. It is now prospected, with drift or level, at the depth of 60 ft. from the surface. This ledge is fully 500 ft. long. Another at the depth of 140 ft., has been run 100 ft. The ledge averages from 10 to 12 ft., and with only a sufficiency of water for running the 10-stamp mill 6 or 7 hours a day, and crushing and running every thing without selection between the 12 ft. walls the yield has been most gratifying, and advances the mine to a high standard. The "Stonewall's" returns have arisen from average rock.

SONOMA COUNTY.

DISCOVERY.—*Sonoma Democrat*, Feb. 22: Two and a half miles south of Cloverdale, near the railroad track, opposite the old grave yard, a man named Savage and Joe Dougherty have located a gold quartz claim which prospects brilliantly and promises well for the discoverers. The Eureka Mining Co. has been organized to develop the mine. A ledge of 6 ft. is well defined, the crops of which assay \$12 per ton. Surface diggings were worked in the same neighborhood about a year ago which paid \$3 per day to the hand. A later assay of rock taken from the mine shows a yield of \$33.50 in gold to the ton.

TULARE.

WHITE RIVER MINES.—*Cor. Visalia Delta*, Feb. 20: I visited these mines a few days since, and the prospects for rich developments are very flattering indeed. First in importance is the Eclipse Ledge, employing 20 men, taking out ore that pays from \$30 to \$40 per ton. The mill (5 stamps) is undergoing repairs at present. The ledge is well defined, and has an average width of 2 ft.

MR. ARCHIE DONALDSON, is working 4 men in the Arnold mine. Rich developments are expected, and there is every indication of a good mine.

A new discovery has lately been made by Messrs. Biggs and Emerson, 7 miles above Tail Holt, and 300 yards from White River, of the Green Monster Ledge, over 100 ft. in width, it has 2 ft. of solid ore on one side which assays over \$40 in gold.

TUOLUMNE COUNTY.

INDEPENDENT. Feb. 22: Table Mountain, Alpha Co. is now digging up as handsome a bank of gold-bearing gravel as ever delighted the eye of a gravel miner. It is from 4 to 5 ft. thick, and fully half its bulk consists of large, well-washed boulders. At the end of the third week from the time of breaking ground the hardest kind of blasting rock was encountered. They then mounted the rock, and running a crescent-shaped drift to the spot they were aiming at, struck good gravel and gold in five days of 24 hours each. There was no further doubt of the richness of the mine.

OMEGA.—A bedrock tunnel was started over 16 years ago, and with a few interruptions the slow and expensive work of blasting through this solid stone bowels of the mountain has been carried on ever since with wonderful pluck, perseverance and energy. Last week the work was given up as hopeless. The tunnel is evidently too low to strike into the channel of the mountain.

PATTERSON.—The purchase has changed the appearance of things round the neighborhood very much. A fine office and other buildings have been erected. A 10-stamp mill will also soon be completed, with additional 10 stamps to be built immediately. In the gulch, a few hundred feet above the mill, two tunnels can be seen in operation, driven into two different hills, but opening into the same vein. The first tunnel we meet has a very hard rock, but worked without interruption, 8-hour shifts, intending to tap the vein 120 ft. deep. Above this tunnel, and on the slope of the hill is a shaft also in full blast, to intersect the tunnel below, for ventilating the mine and other purposes. A few hundred feet up the gulch we come to the other tunnel, closed up for several years, but is now being re-opened, substantially timbered, and will soon be ready to take out rock for crushing. The vein in this tunnel has been worked extensively in one place several years ago, but still shows plenty of rock in sight, apparently equally as good as the rock previously taken out.

Nevada.

ELY DISTRICT.

ALPS.—*Pioche Record*, Feb. 16: About the usual quantity of ore is being taken out of the mine at the bottom of the lower level. The winze from the same level has improved greatly. The ore breast now being fully a foot and a half in width. This is a development from a seam of only an inch in width, which was struck about 3 weeks ago and improvement continues. There are now at least five veins ore on the dump.

PRICING.—There is a vast amount of first-class ore out. Its character is best shown by the average car-sample assay, which is of ore hoisted through 16 consecutive days, the return being \$20 to the ton.

EXCELSIOR. This mine is certainly improving in all parts. There are now 200 tons of first-class ore on top, and hoisting continues, from 8 to 9 tons being dumped daily. The last ore drilled pulped \$150.

PAOE AND PANCA.—The drift is now in well on to 600 ft., and the rock is growing more metalliferous very perceptibly.

PARAN.—Main shaft is now down 80 ft., following the ledge the entire distance. The vein is fully 20 inches in width, and the ore looks well.

CHIEF.—The new shaft below the 90-ft. level has improved very much the past week. There are now about 6 inches of very fine ore on the foot-wall, and the ledge is about 3 ft. wide between the walls.

LA PAZ.—Work continues on this mine with improving indications—the improvement being very marked. A series of rich veins seem to be converging, and those touching the ledge are very rich.

PEATINE.—Work on the cross-cut from the 200-ft. level continues, with very flattering indications.

MAZEPA.—Usual force at work sinking the winze, which is now down about 70 ft. The mine improves as depth is attained.

ORIENT.—Work continues in the drift, which is now 75 ft. The contractor tells us that the indications have greatly improved.

SILVER PEAK.—The incline maintains its average width and the ore its average richness.

PROSPEX.—Sinking in the new shaft progresses finely; it is now down 310 ft. The average progress is 3 ft. every 24 hours.

CHAPMAN.—Drifts are being run from the 360-ft. and the 430-ft. levels to tap the ledge; but it has not yet been reached in either drift.

HUMBOLDT.

MANTROCK.—*Silver State*, Feb. 22: This is a continuation of the Arizona proper. About 250 ft. from the surface we arrived at a point where ore is being extracted at present. A slope, 150 ft. long and 50 ft. high is open on this level, the average width of the ledge being about 2 ft., carrying milling ore principally. From this level an incline shaft, 70 ft. deep, is sunk on the vein. At the bottom of this shaft a level is being run for the purpose of opening another slope. At this point, the deepest yet reached, the ledge is very regular and less broken than nearer the surface, and carries a much greater proportion of shipping ore. Retracing our course to the mouth of the incline, and proceeding a considerable distance in a southerly direction on the main level, we reached a point in the Silver mine where work is being prosecuted. The ledge at this point is looking well and is yielding both shipping and milling ore.

AMAZON.—Wending our way through inclines, levels and shafts, compared with which the mazes of a labyrinth were but a plain road, we reached a level 300 ft. west of the main tunnel. This level is 380 ft. long, and the ledge is from 2 to 5 ft. wide the entire length, exclusive of a chamber about 25 ft. long, where the ledge is from 10 to 15 ft. thick. There is an immense quantity of ore in sight at this point, the "backs" extending toward the surface 300 ft. Proceeding to the main tunnel, about 1,200 ft. from its mouth, we descended an incline 70 ft. deep from the level of the tunnel. At the bottom of this incline a shaft is being run south. The ledge exposed by this drift is from two to four ft. wide, and the ore is impregnated with native silver.

HENNING.—The working force on the Henning has been increased; 21 men are now employed. Developments have demonstrated beyond doubt that it is a valuable and permanent mine.

RYE PATCH.—The Butte mine is running steadily, and has all the ore it can possibly crush from the Butte mine. Work has been suspended for several months on the Alpha mine, partly owing to litigation. There are 3 mining companies now actively engaged in prospecting, with fair prospects of success. The Lincoln, owned by Cody & Co., on which work is now prosecuted, is a good vein, and has yielded considerable ore. The vein carries a great deal of water, which made the working of the mine by shaft very expensive. A tunnel is now being run to the level of the vein, at a depth of 300 ft., and save the expense of hoisting water.

WASHOE.

JUSTICE.—*Gold Hill News*, Feb. 22: South drift still in fine looking quartz, and prospects at other points very favorable.

CROWN POINT.—Yielding about as at last report. The mine looks splendidly at all points, especially so at the 1,300-ft. level. At this level a cross-cut east is started from the third drift, at the belcher line, which is now in about 10 ft. in very rich ore. The drift north at this level is still in good ore and a cross-cut is started from it to the east, which is 7 or 8 ft. in good ore. The main incline is still sinking and the drift south from it at the 1,400-ft. level is driven ahead energetically.

BONORA.—Daily yield, 380 tons. This mine is yielding unusually well at present, and the prospect is bright. The receipts will foot up to \$500,000 or more this month. The ore-breasts at the 1,000, 1,100 and 1,200-ft. levels hold out finely, and a general improvement in the character of the ore is noticeable. The 1,200 is looking and yielding especially well. The drift at the 1,300-ft. level from the Crown Point mine has passed into Belcher ore-body, which is of very rich character at that point.

Work is resumed in the Empire mine, under the active supervision of Superintendent Archie Bonland. At the 1,600-ft. level, toward the south end, some very good ore is found, which assays as high as \$500 to the ton. The body is 25 or 30 ft. wide.

SAVAGE.—The incline is down below the 1,700-ft. level and the new 1,700-ft. station is nearly completed. About the usual amount of ore is being extracted from the upper levels.

HALE & NORCROSS.—The yield of the ore-breasts between the 8th and 9th, and 9th and 10th stations, continues good, and taken altogether, the prospects of the mine are quite encouraging.

COLLIER POTOMI.—Daily yield, 40 tons of ore, the assay value of which is \$33 per ton, showing a large decrease in the daily yield, which is mostly owing to inability to get the ore hoisted to the mills, the dumps all being full.

YELLOW JACKET.—The main drift east, at the 1,400-ft. level, meets with no sign of the east wall. The 1,300-ft. level has reached the north line, and the cross-cutting at that point develops some very good indications of a valuable body of ore.

GOULD & CURRY.—The main east drift on the 1,500-ft. level is again making fair progress, the water in face gradually decreasing.

CALIFORNIA.—The northwest cross-cut from the main north drift has developed a fine body of good milling ore, which is being hoisted to the surface as fast as the drift progresses.

SILVER HILL.—The main north drift at the first station is still driven ahead, the face in good ore. Sinking the incline is making excellent progress, the rock in the bottom working well.

SENATOR.—The Co. have been compelled to shut down their works for the last few days on account of their being unable to get wood, but the furnaces have been so altered as to burn coal, and they expect to resume work shortly.

STERNA NEVADA.—Daily yield 55 tons of good milling ore. It is with great difficulty that sufficient wood can be obtained to keep the mill running.

SILVER CLOUD.—The ore-breasts at the first and second stations, are looking and yielding as large a quantity of good ore as at any time heretofore.

BUCKEYE.—A fine body of good ore 5 ft. in width has been developed in the raise, 200 ft. south from the first station. The mills were obliged to again stop work day before yesterday, on account of the impossibility of obtaining the necessary supply of wood to keep them running.

JULIA.—The main east drift, on the 800 ft. level, is making the usual headway, with no water in the face. In the west drift, on the 1000-ft. level, the rock is working well and water does not interfere.

VICTORIA COY.—The main north drift on the 1167-ft. level from the Gould & Curry shaft is making excellent progress, the rock in the face working well. Sinking the shaft is making excellent progress, the rock at the bottom working soft and well.

ARIZONA AND UTAH.—The shaft is down 204 ft. the rock in the bottom working well and the sinking-making excellent progress. Strata of quartz and clay are continually encountered as the sinking proceeds.

KENTUCKY.—Daily yield 30 tons of good milling ore from the old upper workings.

WOONVILLE.—At the third station the north drift is in 46 ft. and the south drift 64 ft., the ore body in each of the drifts continuing as large as heretofore, and the assay very high in gold.

SURRO TUNNEL.—Total length 3,640 feet. Work progressing as usual.

WHITE PINE.

ROBINSON DISTRICT.—*White Pine News*, Feb. 22: The mines are looking better than ever before, and work on them is only delayed by the inclement weather of the last few weeks. J. M. Ogden, Superintendent of the Canton Co. is expected to arrive soon, and will immediately commence the erection of furnaces on a large scale. Indications point to that section as one of the most promising of all mining camps outside of Hamilton.

Arizona.

MINING ITEMS.—*Arizona Miner*, Feb. 15: The gold dust brought in town this week from Lynx Creek, is in the neighborhood of \$1,000. Buffalo Joe went over there recently and struck a claim out of which he has washed about an ounce a day.

A. C. Williamson and other gentlemen brought in some very rich rock from the Star Eagle, in Bradshaw. The ore looks like Tiger and Benton combined. It is rich in both gold and silver.

During the past 2 months several shafts have been put down upon the War Eagle, Tiger and other lodes, and that the ledges in said new shafts, are good.

From the Hassayampa there are very favorable reports. J. A. Anderson and his partner have struck rich placer diggings in a bar not far from Norton's Carters' mill. All the miners are sluicing and taking out the good yellow gold in paying quantities.

Mr. Allen Cullumber brought up recently, from Walnut Grove, several ounces of gold, the proceeds of a few tons of Big Rebel ore, recently worked in his little mill. He is now taking out richer ore, and will soon be here with a larger lot of dust than that which he recently brought up.

Near Weaver, the Marcons Company are working with their usual vigor. They have now the cream of 6 tons of pulverized ore in their arrastras and intend to keep on crushing until the last of next month.

From Wickenburg the news is quite cheering.

YUMA COUNTY.—We have heard that Mr. Berger had, so far, failed to extract the gold from the mine he has been working, near Ehrenberg, which mine is rich in floor gold.

MOHAVE COUNTY.—Mines of great richness are found on every hand. Since the discovery of the Gunsight mine, in Cerbat Valley District, many other mines and extensive ledges have been discovered in the same district. A very rich discovery was made by J. R. Boner and company of this town, on the north side of the Wapiti Mountains. The first location is named "The Boner." This ledge is 12 ft. thick and wide, and the rock assays from \$300 to \$1,000 per ton. The next location one-half mile south, is named the "Dean." This rock assays from \$17 to \$1,000 per ton, and the ledge is from 8 to 9 ft. thick. The next location is about 1 mile south. The rock is of the same character as above described, and the ledge is here 12 ft. in thickness. In all these locations horn silver and native silver are present in abundance, without the presence of any rebellious ores.

Agenteleman just up from the Gunsight mine reports said mine as rich, or richer, than when I last wrote you. We are now shipping ore from the Gunsight to San Francisco.

Col. Baker's furnace and reduction works, at Chloride, have proved under his excellent management, a complete success.

Colorado.

CARBON MINE.—*Central City Register*, Feb. 6: This mill, in the last week in January, yielded silver bullion to the amount of \$5,050.19; during one-half each of the first and second weeks in Feb., the yield was \$13,645.49, coin value, making the sum total for the two weeks, redundancy value, \$22,695.68. The mill has but 15 stamps. The average yield from these is \$3,000 per day. As the Carbon mine which supplies it, is producing an average of 25 tons per day, the mill has been found much too small to keep up with it, and Mr. Breed has therefore resolved to double its capacity. The value of the ore ranges between \$160 and \$400 per ton. The best quality is worth from 1,200 to \$2,000 per ton. All the extraneous material from 5 ft. wide to 10 ft. to the mill without assorting, and all crushed together.

Montana.

NEW TUNNEL.—*Deer Lodge Independent*, Feb. 8: A company was organized to build a tunnel a few days ago and work commenced on a tunnel under the mountain north of the town. Some very rich float ore has been found on the hill and the projectors hope to strike the vein from which it came.

VIRGINIA CREEK.—The mines are in the gulch and about 10 ft. deep, gold of good quality, both fine and coarse, nuggets worth \$10 having been found last season. The mines have averaged for 2 years not less than \$10 per day to the hand, and the pay streak is from 40 to 100 ft. deep.

ROCKY AND SILVER BOW.—Nelson Wolverton has been engaged for several weeks in the construction of a ditch to carry water from Silver Bow creek, at a point two and a half miles above Rocky city, to the bar and hill diggings lying north of Rocky and Silver Bow. The mines covered by the ditch were discovered last summer and pay from \$5 to \$10 per day.

BEARTOWN.—Chas. Schmitt & Co., Jas. Brannan & Co. and W. Grimes & Co. are making from \$9 to \$12 per day clean "gulchable" dust; which is more than average for placer mines located within 30 miles of the summit of the Rocky mountains, in latitude 46 degs 50 min.

CHEERY CREEK.—*Cor. Avant Courier*, Feb. 15: On the Eberhardt shaft has been sunk to a depth of 83 ft., and the ledge at that depth shows a 3-ft. vein of ore, some of which is exceedingly rich. The Enclosed is open to a depth of 50 ft., with the ore improving as greater depth is attained. The Davis lode is looking better than at any time since discovery. The shaft on this lode is down 45 feet, and the proprietors are sanguine of being independently rich in very "short order."

About 4 weeks ago George W. Resford found a new ledge 5 miles east of the camp, situated in the main belt of the range 20 ft. in width, which yields, by actual working process \$80 per ton. The rock was worked by the Turner process in Harper & Co.'s mill at Silver Star. Messrs. Harper & Co. also worked 2,500 pounds of average rock from the Eberhardt mine with a net result of \$218 per ton.

Effect of Gold Discoveries.

Since the days when the sons in this tale were rewarded for obeying their father's dying request to search for treasure in the garden, the precious metals and stones have been wonderful agents in advancing wealth, civilization and colonization. The utilitarian who regards personal adornment, when it assumes the shape of carrying metals or stones in one's ears or nose, or slave-like chains around one's neck, are remnants of gross barbarism must still admit that the artificial value placed upon precious metals and precious stones has been the chief cause of discovery and colonization. Without going back to the days when ships went from Palestine to Tarsish, we may touch upon some main incidents of which we have a complete history and glance at the influence of the precious metals on the history of the world. To tap the wealth of the Indies, to find the mines from which the gold for Solomon's temple was dug, was the object alike of the great father of discovery and the succession of bold Portuguese navigators who spread along the Western Coast of Africa, doubled the Cape, and who have left their names in India. Love of gold was the origin of the demolition of human sacrifices and cannibalism among the Aztecs, and the cause of the fall of the Inca Power in Peru. But the effects of discovery of gold in our age have been more wonderful than any which have preceded them. Some of us can recollect Texas and California when people were few and far between, when the population consisted in great measure of out-lawed Yankees, of half-caste Roman Catholic priests and the most wretched and faithless semi-Christian Indians. The land was good and inviting, and, as in Italy, men seemed to be the only growth that dwined there. But soon the cry of gold reached the utmost parts of the earth, and drew people from the Old World and the new, from China and from Germany. Gambling and speculation spread the news. Every outrage rendered the place more famous. San Francisco, from being a wretched monastery, grew as few towns have ever grown. Its isolation was felt at Washington and New York. Hence the Pacific Railway, the steamers to Shanghai, Hongkong, Australia, Japan and New Zealand. Within our own recollections an exploring party went from Tasmania to Port Phillip and returned with the impression that the time had not arrived for planting a colony there. A small one, however, was planted, but dwindled until the surplus population of California, enthusiasts from England, and the Chinese were drawn to the gold fields of Victoria. The new fields had attractions alike for the lovers of adventure and the lovers of gold. There grew into early maturity the fine town of Melbourne; there industries, common to all Australian colonies, developed themselves, and next to the Dominion we may call Victoria the finest of our colonies. The great wheat fields of North America remained the home of the buffalo and Indian hunter until gold fields drew men from England and the States. The isolation of British Columbia from the rest of the world has, however, prevented such advances being made in prosperity as its mineral and agricultural wealth would justify us in expecting. But it is the parent of the North Pacific Railway, the future road from England to China. The land of the Griquas and the Free Orange State in South Africa have caused hundreds of blunders to be made in the Colonial Office and thousands of inconveniences to the Cape Government until the diamond fields were discovered and peopled by men who thought no more of a Griqua, a Dutch Boer or a Hottentot than of a plain English Digger. Then the Colonial Office stepped in and gave to the diggers such liberty as they were prepared to fight for.

So far the gold fields have been found where they have done the most practical good. If we could have pointed out a place out of India where we should have liked the next gold field to be found, we should have said near Port Darwin. The South Australian Government has long endeavored to turn the northern territory to account. It was hoped that it would become the great horse-breeding colony of India, and that it might become a colony partly of natives of India and partly of Europeans, and thus the northern portion of the great continent of Australia, as well as the southern would soon become settled. And now news comes to us that gold in large quantities has been found at this very place. Thus gold discoveries will speedily cause the far off and unknown portions of the world to fill up and become the prosperous homes of millions.—*Overland Athenaeum and Daily News.*

LEAD, next to iron, occupies the most important place in the mineral products of Missouri. The lead mines are now only partially developed, but they cover a vast area of territory, and will in time prove a source of great prosperity to the State. Foreign pig lead was for many years imported into St. Louis, but the quantity gradually decreased, falling in 1869 to 7,857 pigs, and to nothing in 1872. During the past year the receipts of lead at St. Louis amounted to 285,769 pigs, or 22,882,650 pounds of which 20,427,000 were produced in Missouri. The exports of lead from St. Louis, in 1872, amounted to only 4,718, 223 pounds, leaving 18,164, 427 pounds retained for home consumption. The soft brands of Missouri lead are chiefly used for the manufacture of white lead, rivaling for this purpose the best imported pigs.—*Iron Age.*

Fish Culture.

The artificial culture of trout is a subject which has but recently began to attract any attention on this coast, although in the Eastern States it has been carried on extensively. A number of plans have been devised for making the fish spawn naturally, in artificial races built for the purpose. One of the best of these was the invention of Hon. Stephen H. Ainsworth. It consists of a race of any length from ten to fifty feet and from two to six feet wide, according to the number of trout to be used and the amount of water to supply the pond.

For large trout the water should be two inches deep at the upper or supply end, and fifteen inches at the lower end where it empties into the pond, with a gentle current its whole length. This will give good spawning depth to the water for trout of all sizes from six to twenty-four inches long. A race only three feet wide and from fifteen to twenty feet long, will be ample for a pond of one thousand or eighteen hundred trout.

To the bottom of the race are fixed fine wire cloth or screens, a finer and a coarser one, for the spawn as it is deposited by the parent trout, to fall through; but which cannot be well de-

scribed for want of space in our columns, nor can their management be made plain without suitable engravings. We must refer the reader therefore to the popular works of the day on this subject.

Our object in speaking of this invention is to contrast it with a greatly improved one, The Ainsworth races, though answering perfectly in making the fish spawn naturally, are nevertheless attended in their management with considerable labor and exposure. This latter ob-

jection was ingeniously surmounted by Mr. A. S. Collins the partner of Seth Green, the famous fish culturist of New York, in a modification of the Ainsworth races, known by the name of the Roller Spawning Box.

This improved roller spawning box for taking the naturally impregnated eggs of brook trout, salmon, etc., is shown in the accompanying cuts. Figure 1 is a spawning box with a portion of its side removed. A, is a double row of coarse wire screens; B, an apron of fine wire cloth; D and F, are both screens. Fig. 2 shows an enlarged view of the front of the same box in which, A, is a double row of coarse wire screens; B, an apron of fine wire cloth; C, apron to receive the eggs; D, a screen; and E, a catch to hold the screen, D, when raised.

In the Roller Spawning Box, the principle used is that of the Ainsworth screens, and the improvement consists in a new and convenient method of collecting the eggs. A double row of coarse wire screens (three meshes to the inch, eight in number, each two feet square, are put together in one frame, eight feet by four. These screens are to be filled with

SIDE VIEW OF COLLIN'S SPAWNING BOX.

FRONT OF SPAWNING BOX.

top of the box, or the top of the box may be cut down until the water will enter on the level at which it is intended to stand over the screens.

A screen, intended to prevent the fish from running beyond the race or getting into the lower part of the box, may extend to the bottom, or be arranged differently; a screen placed at the front of the box is also intended to prevent the fish from getting below. When the eggs are to be taken, this screen is raised on hinges to an upright position, and confined by a spring catch or latch. This confines the fish which may happen to be in the race, and none of them can get below. The pan is then lowered to its position, the roller turned, and the eggs taken. When the operation is finished the screen is again lowered, the button turned, and the work is done.

A concise and greatly extended description of these spawning boxes and the way to use them can be found in a new work entitled Domesticated Trout, how to Breed and Grow Them, by Livingston Stone, A. M. For sale by A. Roman & Co., S. F.

The Cold Weather in Iowa.

Ens. PRESS:—Having kept account of the weather during the last month, I thought it would be interesting to the residents of California to know what kind of weather we have in Iowa during the month of January. The mercury stood as follows:

Jan. 1.....	-18°	Jan. 17.....	-18°
" 2.....	-10°	" 18.....	-8°
" 3.....	-25°	" 19.....	-22°

Clear Lake, Iowa, Feb. 1st, 1873.

M. H.

Utah Coal for Nevada Mines.

Nevada has a deep interest in the development of the coal fields in Utah; we of Eastern Nevada more particularly. Therefore we gladly transfer to our columns the following from the Salt Lake Tribune on this subject:

The Enterprise quotes our recent articles on the availability of the Southern coal region to Nevada by a narrow-gauge road from the coal fields to Pioche, and thence by roads now in contemplation. It concludes thus:

"This coal of Southern Utah might, by means of narrow-gauge transportation, be advantageously used in Southeastern Nevada, but it is doubtful whether it could be delivered in this city cheaper than the Wyoming coal, the transportation charges of which amount to thirteen dollars per ton. The distance would be about the same, with the advantage in favor of Wyoming of but a single handling in shipment. Could three hundred tons of coal be delivered in this county daily at twelve dollars per ton, it would take the place of wood and find a ready sale."

Here, then, is a problem for narrow-gauge men to work out and, according to our view, well worth the working out, too. Three hundred tons of coal a day delivered in Storey county, Nevada, at \$12 per ton, or \$3,600 per day, is an amount of trade worth some exertion to secure, more especially when the demand is likely to be permanent, as the Enterprise states "it is doubtful whether coal, of a marketable quality, will ever be found in Nevada."

The only competition to be considered is, as the Enterprise states, that of Wyoming, with Evanston as the point of shipment—688 miles distant from Virginia City. Now the distance from our Southern coal fields to that city, via Pioche, Hamilton, Eureka and Austin, is but 540 miles, a clear gain of 148 miles in distance to begin with, while in cost of transportation the advantages are, of course, in favor of narrow-gauge roads. Another important point which must not be overlooked in the consideration of this matter, is the great superiority of the Southern coal—much of which is said to be anthracite—over the Wyoming coal.

In order to secure this trade and avoid the handling, to which the Enterprise refers, it would be necessary to depart from the plan originally proposed by the Tribune, at least so far as a portion of the route is concerned, and run from Hamilton to Eureka 40 miles, Eureka to Austin 75 miles, and from Austin to Virginia City 186 miles. This, although not a direct route, would probably be the best one, as it would embrace nearly, if not quite all the mining districts, and open up the interior of Nevada, besides furnishing a direct route for the shipment of goods from San Francisco to the points named, which would benefit Pioche and Southern Utah greatly. In addition to the coal trade, which is the basis of our article, we look forward with confidence to the time when the vast deposits of iron ore adjacent to the coal will be so utilized that in manufactured forms it will supply the whole interior basin with railroad iron and mining machinery, making that region the Pittsburgh of Utah.

For diversity and extent of mineral wealth Southern Utah and Southwestern Nevada are unsurpassed in the United States, and certainly there is no better opportunity presented for the investment of capital in railroads than the one to connect Cedar City, in Utah, with Storey county, Nevada.

BLASTING "SEAM DIGGINGS."—The El Dorado Republican says, that it has been a subject of much speculation whether or not the "seam diggings" on the Georgetown divide could be successfully blasted by what are known as "powder drifts;" a large majority believing that the numerous decomposed quartz seams in these claims would absorb the force of the blast and thus render it ineffectual. Consequently no one seemed willing to hazard the expense of several hundred dollars in making the experiment. The California Water Company, becoming interested in several of these claims, and witnessing the heavy expense attending the working of these bed-rock banks without the use of powder, determined to try the experiment. Consequently a powder shaft was made in the American Mining Company's claim, better known as the Smith claim, near Spanish Dry Diggings, one hundred kegs of powder deposited there. It was fired last Thursday, with the most satisfactory results; lifting and apparently crushing an area of about one-half acre to the depth of eight feet. It is believed that this expenditure of a few hundred dollars has saved thousands.

SOUTH AURORA MINING COMPANY, WHITE PINE.—The shareholders of this company met in London, December 21, 1872, according to adjournment, and resolved to go into liquidation, and wind up the affairs of the present company, preparatory to the formation of a new one, for the purpose of purchasing and working mines in the neighborhood of the South Aurora. Liquidators (analogous to our receivers) were appointed, and a memorandum of the new association was read, from which it appeared that the name of the new company will be the South Aurora Consolidated Silver Mining Company, (Limited), with a capital of £300,000, (\$1,500,000,) in 60,000 shares of £5 each. Arrangements will be immediately made for buying up the shares of those holders who are not satisfied to join in the new project. The name of the mining property to be purchased is not made public.

USEFUL INFORMATION.

The Primary Colors.

If we look steadily for a considerable time upon a spot of any given color, placed on a white or black ground, it will appear surrounded by a border of another color. And this color will uniformly be found to be that which makes up the harmonic triad of red, yellow and blue; for if the spot be red, the border will be green, which is composed of blue and yellow; if blue, the border will be orange, composed of yellow and red; and if yellow, the border will be purple, making in all cases a triad of the three primary colors.

With a view to throw such a light upon the subject as my limited opportunities would permit, I tried over the experiments by which Sir Isaac Newton came to the conclusion that there were seven primary elements in the solar spectrum, and the same results occurred; I could not separate any one of the colors of which it seemed composed, into two. The imperceptible manner in which the colors were bleended together upon the spectrum, however, and the circumstance of the colors which practical people called compound, being always found between the two of which they understood it to be composed, together with my previous conviction induced me to continue my experiments; and although I could not, by analysis, prove that there were only three colors, I succeeded in proving to my own satisfaction, synthetically, in the following manner:

After having tried every color in succession, and finding that none of them could be separated into two, I next made a hole in the first screen, in the center of the line of the spectrum, and another in that of red. I had thereby a spot of each of these colors upon a second screen. I then, by means of another prism directed the blue spot to the same part of the second screen on which the red appeared, where they united and produced a violet as pure and intense as that upon the spectrum. I did the same with the blue and yellow, and produced the prismatic green; as also with the red and yellow, and orange was the result. I tried, in the same manner, to mix a simple with what I thought a compound color, but they did not unite; for no sooner was the red spot thrown upon the green than it disappeared.—*Hay's Interior Decorator.*

A VELOCIPED RACE.—A fifty mile race on bicycle velocipedes recently took place at Wolverhampton, Eng., between two experienced riders, Moore and Johnson. Moore, the smaller man of the two, agreed to allow his opponent an advantage of two miles in the fifty. The first fourteen miles were run in 59 minutes and 23 seconds, the advantage being in favor of Moore. At the end of the twentieth mile the race seemed to be over, as Johnson was evidently suffering from having repeatedly to force his high wheel with short crank up hill against the wind. Moore, on the other hand, with small wheel and long crank, had no difficulty in making the ascent. On the twenty-seventh mile Moore passed Johnson for the sixth time, who could scarcely now move his vehicle up the short hill, and, on the twenty-eighth mile, Johnson gave up the race. Moore finished the remainder alone, making the fifty miles in three hours 56 minutes and 40 seconds, and running the last mile quite as quickly as the first.

The above practical trial appears to show an advantage in the small wheel and long crank over a large wheel and short crank in velocipede driving.

FOAMING IN BOILERS.—The *Scientific American*, in reply to the queries of a correspondent, "What causes foaming in an engine boiler? Is it dangerous or apt to cause an explosion of boiler? Does steam ever descend under the water in a boiler and force the water up and then take its place?" answers as follows:—"Foaming is caused by the generation of steam more rapidly than it can discharge itself from the mass of water within which it is formed. It may give rise to inconvenience, and even danger, either by carrying water out of the boiler more rapidly than the feed pump can replace it, or by entering the steam cylinder of the engine and creating a liability to accident, when the piston strikes upon it, at the end of its stroke, by breaking crank pin, connecting rod or cylinder head. Steam does not get under the water but is sometimes so rapidly disengaged, at points on the heating surface under water, as to almost or quite displace the water.

FOR LUBRICATING.—It is stated that a preparation, consisting of one part sulphur to twenty parts of refined colza oil, after undergoing a heat of from 130 to 140 deg. for an hour, furnishes an excellent lubricating material for machinery. The sulphur, being a poor conductor of heat, is thought to assist to a considerable degree in preventing heat from friction.

TO REMOVE NITRIC ACID FUMES.—Whenever nitric acid pollutes the air by its vapors, as in sundry branches of industry, all injurious consequences may be obviated by the free use of ammonia. The vapor of the latter, combining with that of the nitric acid, forms a compound which is inodorous and innocuous.

Change the Law of Process.

Reader, did you ever reflect that all you can do in the physical, mental or moral world is simply to direct pre-existing forces to accomplish change?

To illustrate this proposition, let us follow the history of any article of common use, say the shoes on your feet.

Long ago, in the pre-historic ages, the manufacture of those shoes was begun, and only through ages of progress and infinite change have they been wrought. In the time when "the earth was without form and void," volcanic forces were at work upheaving, degrading, plowing miles deep to prepare a soil for the growth of nutritious plants to support animal life. Then, through slow successive stages, animals and men appeared.

Then followed that curious round of intricate and, as yet, very dimly comprehended processes, whereby crude inert matter is converted first into coarse organic forms of life, and through those into such finely organized, complicated structures as the skin of a mammal.

The tanner takes such a skin, and, by direct chemical affinity in his vats and other physical forces in subsequent operations, transforms it into leather. Then the shoemaker follows, directing, by his skill, muscular power and the operation of machines. At last appears the finished fabric, to subserve the comfort of man.

In this simple illustration is obtained a glimpse of the vastness of all cycles of change, only through which can their be any progress, even in little things.

How much more, then, ye impatient for the time to come, must mental and moral progress be slow; sometimes so slow that the onward march seems stopped, or, perhaps, to retrograde? But this is only the view of cursory observers. When the foundations of society are shaken by war, by the abandonment of long-established usage, when almost anarchy prevails, people are often wont to become pessimists, and to exclaim that the world is getting worse instead of better. But all these disturbances are but the settling of the moral crust of society. By and by the disruptive forces will have expended themselves, and the sides of the chasm shall be transformed into gentle slopes blossoming with verdure, and its mountain peaks shall stand never more to be shaken, only we must wait.—*American Artisan.*

NEWSPAPERS.—More copies of newspapers are printed in a year in the United States than in all the rest of the world together. England and France come next, and the two together have half as many as the Yankee Nation. Asia, Africa and European Turkey, according to "Hudson's New History of the Newspaper Press," together do not publish so many newspapers and periodicals as San Francisco alone. We imagine, however, that his information about Asia must be incorrect, for there is considerable intellectual activity among the Hindoos. It cannot be denied that in this great branch of progress, the Americans have taken the lead in a most remarkable manner.

HOW TO INSERT SCREWS IN PLASTER WALLS.—It often becomes desirable to insert screws in plaster walls, without attaching them to any woodwork; but when we turn them in the plaster gives way and our effort is vain. And yet a screw may be inserted in plaster so as to hold light pictures, etc., very firmly. The best plan is to enlarge the hole to about twice the diameter of the screw, fill it with plaster of Paris, sand, as is used for fastening the tops of lamps, etc., and bed the screw in the soft plaster. When the plaster has set, the screw will be held very strongly.

SETTING TIRES.—A mechanic gives the following method of so putting tires on wagon wheels, that they will not get loose and require resetting. Use a long cast iron pan or dish made for the purpose; line the oil is brought to a boiling heat, the wheels are placed on a stick over the dish, so as to hang in the oil, each fellow an hour. The timber should be dry, as green timber will not take the oil.

CEMENT FOR LEATHER.—Ten parts of carbon bisulphide and one part of oil of turpentine are mixed, and as much gutta percha added as will readily dissolve. The surface of leather must be freed, with a hot iron, from fat, and the parts once joined should be well pressed until they are firmly united.

LINSEED OIL.—A patent has been taken out by a party in England for treating linseed and other seed and vegetable oils so as to give to them all the advantages derived from boiling without having recourse to that process, and to retain other properties unimpaired which boiling destroys.

ZINC WHITENESS.—Mix oxide of zinc with common size and apply it with a brush, like lime whiteness, to the ceiling of a room. After this apply in the same manner a wash of the chloride of zinc, which will combine with the oxide, and form a smooth cement with a shining surface.

BY RAIL FROM MEXICO.—A correspondent of the *German Town Telegraph* remarks that before the Centennial celebration can take place we shall have trains running straight through from the city of Mexico to Philadelphia.

PAPER MONEY which cannot be counterfeited is said to have been invented by a Berlin lithographer.

GOOD HEALTH.

Process of Digestion.

Digestion is the process by which food is prepared for conversion into living blood. This conversion of dead matter into living substance is the greatest and most mysterious power of Nature; yet it is effected by agencies so very delicate that our nicest chemistry fails to detect even so many active elements as it finds in a Homeopathic pellet of aconite or belladonna. The gastric juice, which produces this miracle of transformation, is almost tasteless, and it has no pungency whatever. It certainly affords an example of how very small a dose of the appropriate element is capable of making the most fatal changes in the living process of the human body.

It is not balk nor mechanical consistency that determines the digestibility of food; nor can the law for one stomach be treated as the law for all. The gastric juice is, no doubt, prepared in every stomach of such variety as to take up the food elements required by the existing conditions of the bodily organs, and to reject such elements as are not wanted. Hence, "what is one man's meat is another's poison." General directions as to what should be eaten are like the usual conglomerate pill of the quack, designated for all cases, and useful in none.

Generation is a congressional act, in which every organ of the body is represented. Hence, parent peculiarities are transmissible, and delicate stomachs, torpid livers, and the like, pass from generation to generation. No doubt digestion is also a congressional act, the gastric juice being a contribution representing the wants of each organ in the body. It is not, then, the bulk one eats, but the kind of food, which, according as it responds to those wants, sits easily on the stomach and gives good digestion. Dyspepsia is the error of injudicious supplies. Theory avails nothing, and general dietetic rules are mockery. Every man must, by experiment, determine for himself.

Some change of food is imperative. Tea, coffee, cabbage, hot bread, the wheaten loaf, pan-cooked pork, salt meat, pastry, etc., may be retired in turn. Rum and tobacco must not go unchallenged; and all private indulgences may be moderated in the experiment. Three meals a day inflict twelve hours' labor on the stomach. Dyspepsia is, perhaps, its mode of striking for eight hours' work, or two meals a day; and its promise may be honest that it will digest as much nourishment for you in eight hours as in twelve, and do it to the greatest profit of the whole body corporate. Don't refuse it a hearing, but give it a fair trial, with reasonable hopes of the restoration of health and harmony.

Listen to no man who proclaims this wholesome, and that not, unless the counsel come from a physician who can give reasons for his advice. Distrust him who tells you to avoid hard and to eat soft-boiled eggs, because the one is hard to digest and the other easy, and to abhor cheese as indigestible altogether. Dr. Leube, of Erlangen, has thoroughly tested the gastric juice of many stomachs, and he finds ripe cheese more digestible than eggs in any form, and well-boiled eggs are better than soft ones.

We would prescribe good nature as an essential element in the cure of dyspepsia. But we know that, with such sickness (as Burns says): "Tis hardly in a Body's power To keep at times free feeling dour."

Labor, then, to right the body, and the body will right the mind. By a process analogous to the conversion of dead matter into living tissue, it seems as though the living body finds the elements for its mental manifestation; for good nature is the product of a healthful balance among the co-working organs of the body. It is also a peculiar function of Homeopathic medicines to adjust, with the least disturbance, the delicate balance upon which hangs the life of health in the body and sanity of the mind. *Ex.*

A NEW IDEA IN BATHS.—A correspondent of one of the English medical journals has taken a sand-bath, and this is his description of the process:

The patient is introduced into a warm, comfortable room, in which is a bath, fenced round with curtains, filled with sand heated to about 100° to 120°. In this a longitudinal groove (I will not say grave) is scooped to receive the patient, who is wrapped in a sheet, and so protected from contact with the sand. There is a comfortable pillow for the head. Then the bath operator gradually covers up feet, legs, arms and trunk with the warm sand. A bucket of hotter and one of cooler sand are at hand, so that the temperature can be adjusted with the greatest nicety. The feeling of warmth is very agreeable, and the weight of the sand is just enough to cause a pleasant sense of compression and support. After an hour's delightful repose, the patient rises, is refreshed by a sluicing of hot water, and goes away refreshed.

The effect is very different from that of hot water, and still more from that of hot air or steam. There was absolutely no commotion of the heart, nor any of the grilling effect on the windpipe which I have experienced in other baths. Altogether, it seems a good thing when we want to produce measured perspiration and relieve congestion of the internal organs.

A NEW FEVERIFUGE.—The *Constitutional* announces the discovery of a new febrifuge, which has been found an excellent substitute for quinine. As the latter is very costly—too much so for the purses of workmen and peasantry who are so frequently the victims of fever—it will be a general boon if the new drug, which is said to possess all the properties of quinine, and which will cost very little, can be brought into use among the public. M. G. Doray, an apothecary in Saint-Lo, it seems, remembering the good effects in certain fevers of bitter aromatics, as, for example, camphor, conceived the idea of trying the action of the laurel, the leaves of which are at once bitter and aromatic. The experiments were conclusive as to its powers, for according to statements made to the Academy of Science and the Academy of Medicine, three grammes of powdered laurel leaves suffice to work a cure. All the fevers treated by the new drug have given way (it is said) in a few days, and it has even been successful in an African fever of long standing, against which sulphate of quinine has proved powerless. The laurel is common in France, and produces no bad effects, so that if its use were general the French would no longer depend on the New World for quinine. Intermittent fevers are very common in France, so that if the medical profession should adopt the new febrifuge after fully testing its properties, it will prove an immense advantage to the population. The green leaves of the laurel (*Laurus nobilis*) are dried by a gentle heat on the fire in a close vessel, to prevent the loss of the volatile elements, and are afterwards reduced to a fine powder, one gramme of which in a glass of cold water may be taken as a dose. The effects of so simple a drug may at least be easily tested.

FAT AND LEAN.—Meat eaters and vegetarians show in their persons the effects of the diet. The first has the most brain force and nervous energy. A mixed food of animal and vegetable rations develops the highest intellectual powers. A strictly vegetable living ordinarily gives a fair complexion, and amiability and extreme pugnacity when the vegetarian's views in regard to that one engrossing thought of his life are discussed. They are annual-meeting reformers, without ever setting a river on fire. Arabs are a sober, frugal race, rather slender, not tall, conscientious and contentious on religious subjects. They largely subsist on rice, pulse, milk and keimac, something similar to whipped cream, through a vast region of an arid country where they are indigenous. They are not destitute of mutton, goats, camels and game; but they manifest no disposition to feed upon meats, as is necessary in temperate zones or in high northern latitudes. An intellectual man, one of their kindred, who rises to distinction by the grandeur of his mental stature, is extremely rare. The beer and ale drinkers expand and grow fat, but they are not much given to profound researches in science.

DIETETIC HINTS.—Most chronic diseases, and many acute ones, are produced at the table. As a rule, no fluid of any kind should be taken at the table, especially if the stomach is weak. The stomach should never be overloaded; not more than two or three articles should be taken at one meal; no stimulants used before eating; tobacco arrests digestion. Milk is the best diet for infants and children. Tomatoes with cream and sugar are healthy and nutritious. Bread and butter is the staff of life, and easily digested. Too much salt irritates the stomach. Colds are frequently produced by drinking hot tea and exposure afterwards. Late suppers induce heart disease. Pastry and cake constipate the bowels. Boiled potatoes are not so healthy as baked ones. Fruits are to be eaten at breakfast and dinner. The stomach requires much rest to be healthy; purgative medicines weaken the bowels. Cheerful conversation promotes digestion; end anger prevents it.

COLOR-BLINDNESS.—An instrument has been invented in Germany for testing color-blindness. It consists of a rotating apparatus, which moves a disk whose center is a circle, one half black and the other white; outside of this is a ring of violet and red, then the outside ring of violet and green. When rapidly rotated, the centre appears to be colored grey, that is white and black mixed. To a green-blind person the middle ring will appear grey, that being the result to him of a mixture of violet and red. The outer ring will appear grey to the red-blind patient, and the inner grey to the violet-blind. By the use of this instrument, a large number of patients may be simultaneously examined for one or more kinds of color-blindness.

BREATHING FOUL AIR.—When breathing air that is dirty, ill-smelling, or otherwise impure, the breath should be drawn in slowly through the nostrils—never through the mouth. In this way the dust and other impurities are mostly lodged in the passages of the nostrils, from which it is readily expelled, and kept from the lungs. People ought always to breathe through the nostrils. A person's life is, in almost all cases, thereby greatly lengthened.

SOUR STOMACH.—Alkali is used in Allopathy to correct acidity of the stomach; but Homopathy corrects it better by small doses of lemon-juice. "I have known many persons," says Dr. Dio Lewis, "who had long suffered from heart-burn or water-brash, cure themselves by a few drops of lemon-juice after a meal."

San Francisco:

Saturday Morning, March 1, 1873.

Legal Tender Rates.—S. F., Thurs., Feb. 27.—buying 88; selling 88½.

Table of Contents.

GENERAL EDITORIALS.—New Zealand Mining Affairs; Grindstones, 129. Amalgamation of the Precious Metals, 136. **ILLUSTRATIONS.**—An Improved Pavement; Different Forms of Drill Points, 129. Fish Culture, 134. The Probable Periodicity of Rainfall, 137.

CORRESPONDENCE.—White Pine Mines, 130. **SCIENTIFIC PROGRESS.**—An Electrical Tower; Interesting Chemical Experiment; Luminous Tubes; Fire and the Atmosphere; Biela's Comet; The Electric Deposit of Copper; Influence of Pressure on the Spectra of Gases, and on the Electric Current; Conservation of Force; A Fatal Flaw in the Darwinian Theory, 131.

MECHANICAL PROGRESS.—The Canal Navigation Award; Steel Rails; New Process for Plating; Value and Utilization of Water Power; Electricity vs. Boiler Scale; Tinning Cast Iron, 131.

USEFUL INFORMATION.—The Primary Colors; A Velocipede Race; Foaming in Boilers; Change the Law of Process, 135.

GOOD HEALTH.—Process of Digestion; A New Idea in Bathing; A New Febrifuge; Fat and Lean; Dietetic Hints; Color-Bloods, 135.

MISCELLANEOUS.—Resources of Utah—Some of the Principal Mines—Continued; The Mineral Belt of Colorado; Coal in China, 130. Effect of Gold Discoveries; Utah Coal for Nevada Mines; Blasting Seam Digging; South Aurora Mining Company, White Pine, 134. Laws Under New California Code; Fuel at the Washoe Mines; The Iron Mine Sold; A Safety Shoe for Railroad Cars, 133.

LITTLE COTTONWOOD RAILROAD.—A bill to incorporate the Little Cottonwood Railroad and Telegraph Company, as amended and recommended to the Honss Committee on Pacific Railroads, provides for a continuous route from Sandy Station on the Utah Southern Railroad, through Grants City and Tannersville to Alta City, in Little Cottonwood Cañon, with this right to build a branch to the Big Cottonwood, and collateral lines not exceeding twenty miles from this main line; the principal office to be in Pittsburgh, Pennsylvania; this capital stock of the Company \$5,000,000.

TRANSIT OF VENUS.—Our Government will shortly be called upon to give an example of its generosity in aiding the cause of science to the extent of \$100,000. Aean "amendment to sundry civil appropriation bills", a provision has been introduced, providing for the organization, by the Secretary of War, of parties to observe the transit of Venus on December 1874. The amendment authorizes a detail of two vessels of war for the transportation of parties to the Pacific and Atlantic stations, and appropriate \$100,000 to defray expenses.

DEATH.—Mr. A. H. Bangle, the inventor of an improved printing press, died at his residence in Brooklyn, Cal., on Wednesday last. He was a very worthy man.

COAL.—A new coal vein, eight feet wide, has been opened at Widefield on the Denver and Rio Grande Railroad, 12 miles from Colorado Springs.

THE RECEIPTS of the San Rafael and San Quentin Railroad company for 1872 were \$19,152; expenses \$15,435.

COAL is to be used in Pioche from the mine of the Wasatch Co. in Utah, as soon as the roads will permit hauling.

THE WELSH miners' strike is reported to be over and about 60,000 of the strikers have returned to work.

MINING sales in Colorado are quite frequent of late at heavy prices. The Caribou mine is said to have sold for \$1,500,000.

Amalgamation of the Precious Metals.

The recent lecture by Eugene N. Riotté, before the Polytechnic Class on the subject of "Amalgamation—with special references to the Pacific Coast" was an interesting one, particularly to the mining community.

Literature.

Mr. Riotté opened his lectures by referring to the literatures of Amalgamation, saying there were but two works on the subject, both of them already old. One is Wrinkler's—"The European Amalgamation of Silver Ores," published in 1848 and never translated. The other is "Kustel's Processes of Gold and Silver Extraction," published (by Dewey & Co.) in San Francisco in 1863. Although this principles of amalgamation as there laid down are still the same, still the practice has since changed materially.

History.

Far back in the dark ages was known this property of quicksilver to combine with the different metals, but especially with gold and silver to form alloys or amalgams which could again be decomposed simply by heat. This property has been employed to extract gold and silver from ores and products and the peculiar metallurgical operation resulting has been termed amalgamation. At first the process was only used to extract metallic or native gold from gravel, sand, soil, etc., or from sweeping, but it was also employed on ore containing free gold. As the ores to his works grew poorer and poorer, or chemically more complicated, the simple mortars, pots, or pans, elucies, riffles, long-toms, etc., by which the process was carried on, became more extensive. Large mills and chemicals, salt, vinegar, etc., were used in grinding the ore and quicksilver together. At the commencement of the 14th century in one district in Bohemia, 350 gold mills were in operation.

This amalgamation of silver ores did not come into use so early or so generally; only few ores could be worked, as the minrelized silver could not be extracted for a long time; but in the middle of the 16th century, Bartolomeo de Medina, a Mexican, succeeded in this also. Velasco took it to Peru in 1588 and Cordova attempted to introduce it into Austria, but failed. For two hundred years after this silver amalgamation reeted in Europe. In the United States Barhae's process was introduced which employed pans and chemicals. It saved quicksilver but did not get so much silver, as Medinas' method, which caused a successful opposition in America; Von Born obviated this defect by a careful preparation of the ore. He first roasted it with salt and then amalgamated it in copper pans, under which a fire was maintained. The ore was stirred with wooden rakes, and after 20 hours poured into a settler, the gangue worked off, quicksilver streined and amalgam retorted. This is the entire theory as it stands to-day; but this practice has been changed and rechanged.

In 1784, Von Born made some public trials, which foreshadowed a great reduction in the cost of working silver ores. Metallurgical ambassadors flocked to Vienna, and as a result mills were built in many places. Jellert, the director of the reduction works at Freiberg, Saxony, about this time found by experiment that the ore became hot without fire under the pans, if stirred violently in a wooden cylinder. The building of the 40-pan mill at Freiberg was stopped until his experiments were concluded. The mills in Hungary were soon changed from the poisonous, hot amalgamation process to Jellert's process of cold amalgamation in wooden cylinders. And now in 1789 a large mill was commenced, with horizontally revolving barrels devised by Ruprecht, and the best amalgamative process to this day was invented. But all these scientific and practical men based the explanation of so great an invention on fallacy. They thought only metallic silver would amalgamate, and that it was metallic silver that was formed in the Pateo by magistral and in the furnace by salt. Lampadius proved that it was chloride of silver that was wanted, and what had really been formed during the preliminary washing. And to this day we have got no further.

The speaker said that you ought to take this slight sketch and substitute well known names and places in California and Nevada, and you have the history of amalgamation here. The euphousous Alonzo Barhae's process becomes plain "Smith's pans," etc. In speaking of the way things were done

On the Pacific Coast,

Mr. Riotté said: How often may you not hear the remark in regard to the ore from new localities, or new combinations, "If we could only find out how to work our ores;" or, better still, "There is no way to get at the silver;" all of which is very silly. Give the metallurgist the price of labor, wood, salt and freight at any given point, and the way or ways of working can be told with mathematical certainty. Then a test must be made, not by a quack, but by a scientific and practical experimenter, who is at the same time thoroughly honest. The mistakes may all be accounted for. You must remember one little maxim: "Don't build mills before you have ore and don't experiment as to how ore should be worked with a \$100,000 quartz mill, with an ass, or worse, a knave at the head of it. Now let me lay down a few

General Principles of Amalgamation.

First, it is a settled fact that gold needs friction, and silver chemical action. Gold is in a native or metallic state in this ore and can only be extracted in this form. It is therefore necessary to connect it and the quicksilver very intimately to make the two combine or one dissolve in the other; it is a purely mechanical operation and upon its mechanical perfection reests its success. Remember again that only metallic gold will amalgamate, everything to the contrary notwithstanding.

Silver must enter the pans or barrels as a chloride; from this compound it is either precipitated by quicksilver and chloride of mercury and silver formed which is immediately taken off by the surplus quicksilver, or it is precipitated by the iron and simultaneously amalgamated. This is a chemical action, during the progress of which heat is evolved, which like the acid solution of salt, aids the decomposition. Galvanic effects are produced which suffice to explain the results in harrs or pan.

Chemicals added during gold and silver amalgamation are often dangerous, always detrimental and never of any use. Kustel says: "In regard to chemicals, after several months at Col. Raymond's mill on the Cersour river, experience proved that the use of chemicals is entirely useless: I am prepared to prove this by actual experience." Wrinkler proved the same ideas in regard to the large addition of magistral. In gold ore amalgamation any and all chemicals have only the effect of reducing the fineness of the hullion and costs much money.

In silver amalgamation the addition of salt and sulphate of copper seems to hasten amalgamation at first, but is liable to stop it too soon, and then the galvanic reaction necessary, cannot again be produced. No more silver is produced than without them, the hullion is less fine, and quicksilver is lost by "flooding" in proportion to the chemicals employed. A notable exception to this is working slimes from the Comstock. In this case chemicals are employed to advantage, but have a mechanical action. The slimes are, when put in a pan and mixed with water, difficult to "temper," that is, to mix to such a consistency that the action of the mullers of the pan will throw the quicksilver finely divided into the ore. No results can be obtained from a pan that is not "tempered." We have here, as before, an entirely mechanical operation to deal with. The particles of gold and silver must be brought in contact. Now a mixture of salt or sulphate of copper, or either singly, finely divides the quicksilver that is shaken with it, which is what we wanted. No matter how poor the workmanship in tempering you have become independent of it. In the

Mechanical Appliances

For the use of Barhae's or Von Born's process, we have made immense strides recently. Instead of 200 or 300-pound pans we have the Stevenson 6,000-pound, or even Park's 20-ton cast iron pan, that finishes a charge every six hours.

In raw amalgamation, fancy, or the size of the purse still govern the size of the pan. The simplest and cheapest is the best. Don't be deceived by the catch-word "it is a great grinder." This is just what you don't want. Powder your ore under stamps, which is the machinery for crushing, not the pan. Stamps will crush for one-tenth the cost in one-tenth the time. The pan that "is a great grinder" will also grind your quicksilver and make it "flour." Rubbing would be a much more needed faculty; this is what is needed in a pan. For

roasted ore the selection of pane is narrowed down to one or two. Only the "Combination pan" contains all points.

"Future Processes."

May we hope that the days of amalgamation of roasted ore are numbered. We are now 50 years behind the age. Nowhere, except here, is it now practiced; melting furnaces and leaching tubs have long ago superseded the hulk machinery needed for amalgamation. Where we can chloridize up to 95 per cent. and mors, we are but amalgamating up to 90 per cent. Two, three, and even ten per cent. of the silver already in our grasp is thrown away by this costly, ponderous, but simple process. We know how to do this, and to learn anything new is fearfully difficult. Let us raise up a generation of young men who are willing to devote a life's study and purpose to mining and metallurgy and we will soon overtake and pass the balance of the world.

Australia and New Zealand.

The wonderful island continent of Australia, with its neighboring islands of Tasmania and New Zealand, contain on their shores, washed by the waters of the Pacific, many fine ports and harbors now the seats of flourishing cities and towns. The area of Australia, Tasmania and New Zealand is about equal to that of the United States, but the circumstances of soil and climate are very different. By much the greater part of Australia is hot and dry with a deficiency of navigable rivers, and of arable land. There are immense tracts, however, on the east and north suited to the culture of Sugar, Cotton and other tropical productions, a tract as large as the whole of the Pacific Coast. Three-fourths of the remainder will have to be devoted to sheep husbandry. From this may be predicted the nature of the commerce that will in future subsist between San Francisco and the trade ports of Australia. We shall have to supply a population as large as the United States with Wheat and all the various productions of the temperate climates of this Coast, and we shall in return be purchasers of their Cotton, Sugar and Wool, which we will manufacture and distribute abroad to the world.

QUICKSILVER.—If Napa county proves as prolific in quicksilver as it is in "quicksilver mine" we will surely see the speedy downfall of the Rothschild-Barron monopolise throughout the world, and especially on this coast. The product of the county is as yet, however, quite limited, but judging from recent reports it will be materially augmented before long. We are informed by the Register that a vein of ore was struck a few weeks since that promises to be the richest yet found. It is being drifted upon and shows a free show of rich ore. If even a very small proportion of the locations made are worked and prove by their product to be valuable, Napa county ought to do well in the quicksilver trade, without having to put her minss in the London market.

COPPER PRODUCT OF LAKE SUPERIOR MINES.—From a detailed statement of the production of copper of Lake Superior mines in the Marquette Mining Journal, we learn that the total for the year 1872 was 15,166 tons, a decrease of 905 tons from 1871 when the production was 16,071 tons. This total copper (mineral) product of the mine from 1845 to 1873 is 176,395 tons. An approximate statement of ingot copper produced and its value from 1845 to 1872 inclusive gives a total of 135,075 tons, valued at \$76,303,320. The dividends declared by mining companies in 1872 amounted to \$3,390,000, while the assessments were only \$190,000, leaving an excess of dividends over assessments of \$3,200,000. The total dividends declared by mines at Lake Superior aggregate \$11,910,000.

A SEQUEL TO THE DIAMOND FRAUDS.—Everybody remembers the big diamond fizzle of last year, and meet probably the names of prominent parties, with ewindlers or ewindled, who had any connection with it. The whole affair was thoroughly investigated by the press and comments made upon the actions of those who were at all connected with the affair. Wm. M. Lent who alleges that he lost by the whole transaction the sum of \$250,000, has sued the Territorial Enterprise for publishing an alleged libellous article which accuses Mr. Lent of being fraudulently implicated in the Arnold etock diamond swindle. Mr. Lent aeks for \$15,000 damages from Jas. T. Goodman, editor of the Enterprise.

A HEAVY snow slide occurred in Little Cottonwood on the 26th ult., and the roads blocked but no lives lost.

The Probable Periodicity of Rainfall.

At the last meeting of the California Academy of Sciences, the President, Professor George

Davidson, of the U. S. Coast Survey, read a paper on "The Probable Periodicity of Rainfall," which was accompanied with diagrams illustrating the average of rainfall in California for 23 years, and which, as it is a subject of great interest, we publish with this cuts. Professor Davidson said: Many attempts have been recently made to establish a periodicity of rainfall commensurate with the eleven year period of the solar spots. In limited cases the law has appeared to prevail, but in cases as apparently reliable the results have been adverse. In an extended series of observations of the rainfall in England, stretching through 150 years (British Association Report for 1866) no such maxima and minima could be deduced; and in a series of observations, over various parts of the globe, gathered by G. J. Symons, in number 165 of *Nature*, the same want of law is manifest; in fact, where maxima of rainfall should be expected, we find minima, and vice versa. These tables are, however, too limited to deduce a general law therefrom. The materials are at hand for a much more comprehensive treatment of the problem.

But if there is a law in such cases isochronous with the exhibition of the sun spots, it must be qualified by other variable functions than rainfall; such as the temperature and pres-

sure of the atmosphere, the amount of aqueous vapor in the atmosphere, the direction and force of the winds, and the climatology, not only of the adjacent ocean, but of the sources of the great currents that cross the ocean. For example: if the rainfall of the Western Coast of Europe is assumed dependent upon the same causes which occasion the solar spots, the epochs of the maxima and minima rainfall would not coincide with those of the solar spots, because the precipitation of rain and the temperature of the seaboard of Ireland, Scotland, Norway, Iceland, Spitzbergen, etc., depend upon the temperature of the Gulf stream bathing those shores; and the waters of the Gulf of Mexico heated to a maximum at a given epoch would not reach the coast of Norway for possibly a year. The same is true of this Coast; the heated waters of the great Japan stream, at their point of departure at the Island of Formosa do not reach this Coast for more than a year. Thus whilst these superheated waters are delayed one year in reaching their destinations, the climatic conditions of the Coasts of Norway and of California, supposed to be governed by a regular law, have been changed and the problem is complicated and masked by these changes in the nearer effects of the climate of the adjacent continents; and in the European case, of the Polar Basin.

If there is a law of the rainfall, there will naturally be a similar law for the temperature and pressure of the air and for the winds; but it must be complicated and masked by the influence of great ocean currents, so that the problem instead of being simple, as it first appears, is in reality very intricate.

An attempt has been made to give an eleven year period to the cyclones in connection with the rainfall, but evidently upon insufficient data, for Mr. Meldrum only claims that a supposed periodicity has been made out. Lockyer (*Nature*, No. 163) in discussing Mr. Meldrum's records and others at Madras and the Cape of Good Hope, sees in them indications of a periodicity, but his discussion is merely tentative from insufficient materials and is not satisfactory.

The same eleven-year period has been assigned to the seasons of great freshets in California; but we need, what we cannot ob-

tain, absolute observations over extended areas, and not mere reports to aid in its establishment. The statement was common in the west that the greatest freshets occur on the great rivers of the Western States about every ten years.

I have had placed in graphical order the rainfall at San Francisco for 23 years, from Mr. Thomas Tennent's observations and exhibit it to show that we cannot, from it alone, predicate any periodicity. Even the well marked short period of comparatively little rainfall and of clear weather during each of our wet seasons is masked in the averages of monthly rainfall in these years by its not occurring at any well defined epoch. But its existence is well marked and established in the illustration of the monthly rainfall from 1849 to the present.

FIG. 1—YEARLY RAINFALL AT SAN FRANCISCO FOR 23 YEARS.

sure of the atmosphere, the amount of aqueous vapor in the atmosphere, the direction and force of the winds, and the climatology, not only of the adjacent ocean, but of the sources of the great currents that cross the ocean. For example: if the rainfall of the Western Coast of Europe is assumed dependent upon the same causes which occasion the solar spots, the epochs of the maxima and minima rainfall would not coincide with those of the solar spots, because the precipitation of rain and the temperature of the seaboard of Ireland, Scotland, Norway, Iceland, Spitzbergen, etc., depend upon the temperature of the Gulf stream bathing those shores; and the waters of the Gulf of Mexico heated to a maximum at a given epoch would not reach the coast of Norway for possibly a year. The same is true of this Coast; the heated waters of the great Japan stream, at their point of departure at the Island of Formosa do not reach this Coast for more than a year. Thus whilst these superheated waters are delayed one year in reaching their destinations, the climatic conditions of the Coasts of Norway and of California, supposed to be governed by a regular law, have been changed and the problem is complicated and masked by these changes in the nearer effects of the climate of the adjacent continents; and in the European case, of the Polar Basin.

This is on a scale of inches one-half that of Fig. 2. In this the break in the wet season of most of the years is plainly marked, but it does not occur with any regularity as to time.

To arrive at a law of periodicity in atmospheric phenomena will demand a comprehensive scheme of observations over a large extent of the earth and ocean; this scheme to involve all the conditions of atmospheric variations and the local relations of each station to the whole, and be represented in graphical rather than in numerical order.

I believe in the law of periodicity of these phenomena, but it will be found an intricate

FIG. 3—AVERAGE MONTHLY RAINFALL FOR YEARS.

problem and is doubtless involved with such conditions as the lunar cycle of 19 years, etc. As stated in my paper last year upon "the Cosmical Origin of Physical Phenomena on the Surface of the Earth," we must expect abnormal exhibitions of these phenomena from the irregular exhibition of the materials burning upon the surface of the sun; but in a prolonged series of spectroscopic observations of solar phenomena and observations of physical phenomena on the earth, we will eventually arrive at the law of their recurrence.

SENATE COMMITTEE ON PATENTS.—The Senate Committee on Patents have reported adversely on extending Goodyear's patent on hard rubber. The principal application of this is to plates for artificial teeth, and the extension was opposed by most of the dentists throughout the country. The bill to extend Jenkin's patent for combining wrought and cast iron in ornamental railing, cornices, etc., was reported favorably. The committee has declined to consider any further applications concerning patents at this session.

PATENTS & INVENTIONS.

Telegraphic List of U. S. Patents Issued to Pacific Coast Inventors.

[RECORDED OFFICIALLY FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]
By Special Dispatch, Dated Washington, D. C., Feb. 25th, 1873.

FOR WEEK ENDING FEBRUARY 11th, 1873.

RAILROAD TRACK.—Alexander D. Rock, Hamilton, Nev.

STRAW FEEDING ATTACHMENT FOR FURNACES.—David Morey, Watsonville, Cal.

TRADE MARK.

MEDICINAL COMPOUND.—Emil Frese, S. F., Cal.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

CENTRAL PACIFIC RAILROAD CO.—The annual report of the Central Pacific Railroad Company for 1872 shows that the receipts for transportation of passengers, freights, mails etc., exceeded the receipts of 1871 by \$2,836,538. The capital stock of the road is \$100,000,000 of which the amount actually paid in is \$54,283,190. The total amount expended for the purchase of lands is \$906,100; for the construction of the road \$131,609,304; for buildings \$1,126,857; for engines \$2,106,164; for cars \$3,516,208. The amount received for transportation of passengers, mails etc., was \$4,563,551 in U. S. currency and \$7,400,089 in gold coin. Freight transported 948,114 tons. The current running expenses of the road for the year were \$9,271,721. The number of engine houses and shops and of engines and cars, is as follows, to wit: 11 engine houses, 11 repair shops, 184 locomotive engines, 223 passenger cars, 25 baggage cars, 15 mail and express cars, 3,194 freight cars, 110 dump cars, 222 hand cars, 179 section cars, 51 iron cars, 7 snow plows, 2 wrecking cars.

LECTURES FOR WORKING MEN.—The Wednesday evening lectures of Dr. E. S. Carr in the Chemical Lecture room of the State University, Oakland, are highly appreciated by full and attentive audiences. We have never before noted so valuable a course of free lectures delivered by one lecturer. His practical and interesting lessons will prove of much benefit, and he long remembered by his intelligence-seeking auditors.

NARROW GAUGE.—In the Nevada Legislature, Senator McCoy, of Lander Co. has introduced a bill providing for the construction of a narrow gauge railroad from Palisades, near the line of the Central Pacific to Eureka, Lander Co., a distance of about ninety miles. It authorizes Lander County to issue bonds to the amount of \$300,000 to aid the construction of the road.

A SMALL RAILROAD.—At the Royal Arsenal in Woolwich, a small miniature locomotive engine is used to draw trucks carrying altogether about 20 tons of metal. The track has a gauge of only 18 inches. The railroad is intended to supersede as far as possible the transit of heavy loads by contract horses and is of great convenience about the works.

A PROJECT is being discussed of running a tunnel in Lassen county from Willow Creek valley to tap the waters of Eagle Lake, a distance of one mile, which operation will not only supply water for large agricultural operations, but make available, valuable mineral lands now worthless.

THE QUESTION of a narrow gauge railroad from Santa Barbara to Soledad Pass is being agitated by the Santa Barbara Press. The distance is only 70 miles, and the Press says one man, Colonel W. W. Hollister, for instance, could build and own the road, without seeking aid from outside parties.

MEXICO'S FIRST RAILROAD was put in operation on the 1st of January, 1873; it runs from the city of Mexico to Vera Cruz. On some portions of the road the grades are very steep, but the peculiarly constructed engines and brakes allow the trains to make the ascents and descents without difficulty.

FRANCE sent last year 52,000 tons of rails to other countries notwithstanding the natural depression of industry after the late war.

FIG. 2—MONTHLY RAINFALL AT SAN FRANCISCO FROM 1849 TO 1872.

Laws Under New California Code—Taking Effect Jan. 1, 1873.

(Continued from page 106.)

Title I to apply to all corporations, with certain exceptions.)

403. The provisions of this Title are applicable to every corporation, unless such corporation is excepted from its operation, or unless a special provision is made in relation thereto inconsistent with some provision in this Title, in which case the special provision prevails.

Note—

An Act in relation to foreign corporations.
(Approved April 1, 1872.)

(Enacting clause.)

Section 1. Every corporation heretofore created by the laws of any other State and doing business in this State shall, within one hundred and twenty days after the passage of this Act, and any corporation hereafter created and doing business in this State, within sixty days from the time of commencing to do business in this State, designate some person residing in the county in which the principal place of business of said corporation in this State is, upon whom process issued by authority of or under any law of this State may be served and within the time aforesaid shall file such designation in the office of the Secretary of the State; and a copy of such designation, duly certified by said officer, shall be evidence of such appointment; and it shall be lawful to serve on such person so designated any process issued as aforesaid. Such service shall be made on such person in such manner as shall be prescribed in case of service required to be made on foreign corporations, and such service shall be deemed to be a valid service thereof.

Sec. 2. Every corporation created by the laws of any other State which fail to comply with the provisions of the first section of this statute shall be denied the benefit of the statutes of this State limiting the time for the commencement of civil actions.

Sec. 3. Every corporation created by the laws of any other State which shall comply with the provisions of the first section of this statute shall be entitled to the benefit of the statutes of this State limiting the time for the commencement of civil actions.

Wagon Road Corporations.

(Three Commissioners to act with Surveyor.)

512. Three Commissioners must act in conjunction with the Surveyor of the corporation, two to be appointed by the Board of Supervisors of the county through which the road is to run and one by the corporation, who must lay out the proposed road and report their proceedings, together with a map of the road, to the Supervisors who appointed them, as provided in the succeeding section.

(Survey and map to be filed and approved by Supervisors.)

513. When the route is surveyed, a map thereof must be submitted to and filed with the Board of Supervisors of each county through or into which the road runs, giving its general course and the principal points to or by which it runs, and its width, which must in no case exceed one hundred feet, and the Supervisors must either approve or reject the survey. If approved, it must be entered of record on the journal of the Board, and such approval authorizes the use of all public lands and highways over which the survey runs; but the Board of Supervisors must require the corporation, at its own expense, and the corporation must so change and open the highway so taken and used as to make the same as good as they were before the appropriation thereof; and must so construct all crossings of public highways over and by its road, and its toll gates, as not to hinder or obstruct the use of the same.

(Tolls, etc., to be collected. Penalty for taking unlawful tolls.)

514. All wagon road corporations may bridge or keep ferries on streams on the line of their road, and must do all things necessary to keep the same in repair. They may take such tolls only on their road, ferries, or bridges as are fixed by the Board of Supervisors of the proper county through which the road passes or in which the ferry or bridge is situate, except that in the counties of Trinity, Shasta, Klamath, Butte, Siskiyou, Del Norte, Plumas, Humboldt and Sierra, the Directors may fix their own tolls; but in no case must the tolls be more than sufficient to pay fifteen per cent. nor less than ten per cent. per annum on the cost of construction, after paying for repairs and other expenses for attending to the road, bridges, or ferries. If tolls, other than as herein provided, are charged or demanded, the corporation forfeits its franchise, and must pay to the party so charged, one hundred dollars as liquidated damages.

(No tolls to be charged on highways or public roads.)

515. When any highway or public road is taken and used by any wagon road corporation as a part of its road, the corporation must not place a toll gate on or take tolls for the use of such highway or public road by teamsters, travelers, drovers, or any one transporting property over the same.

(Rates of toll to be posted at gate.)

516. The corporation must affix and keep up, at or over each gate, or in some conspicuous place, so as to be conveniently read, a printed list of the rates of toll levied and demanded.

(Toll gatherer may detain persons until they pay toll.)

517. Each toll gatherer may prevent from passing through his gate persons leading or driving animals or vehicles subject to toll, until they shall have paid, respectively, the tolls authorized to be collected.

(Toll gatherer not to detain any person unnecessarily.)

518. Every toll gatherer who, at any gate, unreasonably hinders or delays any traveler or passenger liable to the payment of toll, or demands or receives from any person more than he is authorized to collect, for each offense forfeits the sum of twenty-five dollars to the person aggrieved.

(Persons avoiding tolls to pay five dollars.)

519. Every person who, to avoid the payment of the legal toll, with his team, vehicle, or horse, turns out of a wagon, turnpike, or plank road, or passes any gate thereon on ground adjacent thereto, and again enters upon such road, for each offense forfeits the sum of five dollars to the corporation injured.

(Penalties for trespasses on property of corporation.)

520. Every person who:

1. Willfully breaks, cuts down, defaces, or injures any mile stone or post on any wagon, turnpike, or plank road; or,
2. Willfully breaks or throws down any gate on such road; or,
3. Digs up or injures any part of such road or anything thereunto belonging; or,
4. Forcefully or fraudulently passes any gate thereon without having paid the legal toll;

For each offense forfeits to the corporation injured the sum of twenty-five dollars, in addition to the damages resulting from his wrongful act.

(When capital invested is repaid, tolls to be reduced, etc.)

521. The entire revenue derived from the road shall be appropriated; first, to repayment to the corporation the costs of its construction, with fifteen per cent. per annum interest thereon, together with the incidental expenses incurred in collecting tolls and keeping the road in repair. When the repayment is completed, the tolls must be so reduced as to raise no more than an amount sufficient to pay incidental expenses and to keep the road in good repair.

(May mortgage and hypothecate corporate property.)

522. The corporation may mortgage or hypothecate its road and other property for funds with which to construct or repair their road, but no mortgage or hypothecation is valid or binding unless at least twenty-five per cent. of the capital stock subscribed has been paid in and invested in the construction of the road and appurtenances, and then only after an affirmative vote of two-thirds of the capital stock subscribed.

(This Title applies to natural persons as well as corporations.)

523. When a wagon, turnpike, or plank road is constructed, owned, or operated by any natural person, this Title is applicable to such person in like manner as it is applicable to corporations.

(How organized.)

Land and Building Corporations.

639. Corporations organized under Subdivision 11 of Section 286 may raise funds in shares not exceeding two hundred dollars each, payable in periodical installments. Such bodies are known as land and building corporations, and may be organized with or without capital stock.

(May borrow money.)

640. Any such corporation may borrow money for the purpose of carrying out its objects, and may give as security therefor its shares or mortgage upon its real estate.

(Power and object of the corporation.)

641. Any such corporation may purchase real estate and erect buildings for its members, and make loans to its members for the purpose of aiding them in acquiring and improving real estate. Such loan must in all cases be secured on such real estate.

(May insure the lives of members and debtors.)

642. Such corporations may insure, in some life insurance company incorporated

under the laws of this State, the lives of its members and debtors. In case of the death of a debtor or member so insured, the amount recovered on the policy must be applied to extinguish the indebtedness, including the premium paid, and the residue, if any, must be paid to the legal representatives of the decedent.

(What real estate may be owned at any one time.)

643. Any such corporation may purchase, hold, and convey real estate, as follows:

(Liability of shareholders for debts.)

646. Every present and past member of such corporation is personally liable for such proportion of all its debts and liabilities, incurred during his membership, as the number of shares subscribed by him bears to the whole number of subscriber shares; but no past member is liable for such contribution if more than one year had elapsed since he ceased to be a member before suit is commenced, nor for any debt or liability contracted after the time to which he ceased to be a member, nor unless it appears to the Court that the corporation is unable to satisfy such debts and liabilities; nor must any contribution be required for any member or past member exceeding the amount unpaid on the shares in respect of which he is liable.

(Consolidation and transfer of corporation business and property.)

647. Any two or more such corporations may unite and become incorporated in one body, with or without any dissolution or division of the funds of such corporation, or either of them; or any such corporation may transfer its engagements, funds, and property to any other such corporation, upon such terms as may be agreed upon by two thirds of the members of each of such bodies present at general meetings of the members, convened for the purpose by notice stating the object of the meeting, sent through the postoffice to every member, and by general notice, appearing daily at least one week, or weekly at least two weeks, in some newspaper published at the place of the principal business of the corporation; but no such transfer can prejudice any right of any creditor of either corporation.

(Married women and minors.)

648. Married women and minors may be admitted as members and may take and hold shares in such corporations, and may execute all necessary instruments and give all necessary acquittances, and sell and transfer their shares, in like manner as other members.

Mining Partnerships.

(When a mining partnership exists.)

2511. A mining partnership exists when two or more persons who own or acquire a mining claim for the purpose of working it and extracting the mineral therefrom actually engage in working the same.

(Express agreement not necessary to constitute.)

2512. An express agreement to become partners or to share the profits and losses of mining is not necessary to the formation or existence of a mining partnership. The relation arises from the ownership of shares or interests in the mine and working the same for the purpose of extracting the minerals therefrom.

(Profits and losses, how shared.)

2513. A member of a mining partnership shares in the profits and losses thereof in the proportion which the interest or share he owns in the mine bears to the whole partnership capital or whole number of shares.

(Lien of partners.)

2514. Each member of a mining partnership has a lien on the partnership property for the debts due the creditors thereof, and for money advanced by him for its use. This lien exists notwithstanding there is an agreement among the partners that it must not.

(Mine partnership property.)

2515. The mining ground owned and worked by partners in mining, whether purchased with partnership funds or not, is partnership property.

(Partnership not dissolved by sale of interest.)

2516. One of the partners in a mining partnership may convey his interest in the mine and business without dissolving the partnership. The purchaser, from the date of his purchase, becomes a member of the partnership.

(Purchaser takes, subject to liens, unless, etc.)

2517. A purchaser of an interest in the mining ground of a mining partnership takes it subject to the liens existing in favor of the partners for debts due all creditors thereof, or advances made for the benefit of the partnership, unless he purchased in good faith, for a valuable consideration, without notice of such lien.

(Takes with notice of lien, when.)

2518. A purchaser of the interest of a partner in a mine when the partnership is engaged in working it, takes with notice of all liens resulting from the relation of the partners to each other and to the creditors of the partnership.

(Contract in writing, when binding.)

2519. No member of a mining partnership or other agent or manager thereof can, by a contract in writing, bind the partnership, except by express authority derived from the members thereof.

(Owners of majority of shares govern.)

2520. The decision of the members owning a majority of the shares or interests in a mining partnership binds it in the conduct of its business.

Fuel at the Washoe Mines.

As wood in the timber ranges of the Sierra Nevada Mountains is daily becoming more difficult of access, and as the supply is rapidly growing "heavily less," it has even now become a question of no little interest to know how the growing deficiency in fuel for milling, mining and other purposes is to be supplied. We can look for relief in no other direction than to the coal regions of the Rocky Mountains. The slopes of the Sierras will soon be denuded of everything that can be worked up into cordwood, and as we cannot wait for a new growth of timber we must look in some other direction for our fuel. Hitherto there has been some difficulty about getting full and regular supplies of coal from the Rocky Mountain coal regions and our mine and mill owners have for this reason been somewhat backward about adopting it and depending on it for daily use. Now, however, we learn that the Virginia and Truckee Railroad Company have assurances from the Rocky Mountain Coal Company that they will be able to give a supply of coal to this portion of the State in quantity sufficient to make up any deficiency in our full supply that may arise from a shortness of wood. There will soon be an immense demand for coal in all this region, and year by year this demand must increase if our mines hold out as they now promise to do. The season during which wood can be got down off the mountains is short, and every year the woodcutters are climbing higher and higher up their slopes, greatly increasing the distance and difficulty of transportation. It is now proposed to land coal at the depot in this city at \$18 per ton of 2,240 pounds. This may do for a short time, but we must soon have it cheaper. The cheaper it is furnished the more we will take of it. The majority of our mill and mine owners are already preparing to burn coal, and once it is made sufficiently cheap along the line of the Virginia and Truckee Railroad, only that quantity of wood required to be used with the coal, to produce the heat effect in steam-making, will be called for. For this purpose more or less wood

will always be used, provided it can be obtained at a reasonable price, therefore the owners of wood-ranches need not be alarmed at the introduction of coal in our mines.—*Virginia Enterprise*.

THE IRON MINE SOLD.—It is reported that the iron mine near Mohawk Valley, Plumas county, has been sold to a party of heavy capitalists, and it is thought that some very extensive operations will be commenced in the spring toward the opening and developing this vast deposit of iron ore. The company talk seriously of constructing a narrow-gauge road to Reno, or some point of connection with the Central Pacific. That highly renowned scientific explorer, Clarence King pronounced this mine the finest body of ore west of the Rocky Mountains. Should the report be true, we think the company have the most valuable piece of property in the northern part of the State. The timber interests, in connection with the road and the mine, would certainly place the property on a paying basis second to none west of the California line.—*Plumas National*.

A SAFETY SHOE FOR RAILWAY CARS is an invention which has recently been attracting considerable attention at Philadelphia, and which is figured in the last number of the *Journal of the Franklin Institute*. The device consists of strong wrought iron runners affixed lengthwise of the car and upon both sides, so arranged that in case of the breaking of a wheel the weight of the car comes upon the runner, by which it may move along with comparative ease upon the outer ends of the tie. It is said that there is a probability that the device will soon receive a practical test.

It has been ascertained, by sinking a shaft to the depth of 200 feet at its border, that the great Okefenokee Swamp, in Southern Georgia, is underlaid with a bed of bituminous coal. This swamp is a thickly timbered morass, about two hundred miles in circumference and the project has been conceived of draining it.

DEWEY & CO.,

American & Foreign Patent Agents,

OFFICE, 333 MONTGOMERY STREET, S. F.

The best, speediest, and surest method for you to obtain patents, file caveats, or transact any other important business with the Patent Office at Washington, or with foreign countries, is through the agency of DEWEY & CO., PUBLISHERS OF THE MINING AND SCIENTIFIC PRESS, SAN FRANCISCO, an able, responsible, and long-established firm, and the principal agents on this side of the continent. They refer to the thousands of inventors who have patronized them, and to all prominent business men of the Pacific Coast, who are more or less familiar with their reputation as straightforward journalists and patent solicitors and counselors.

We not only more readily apprehend the points and secure much more fully and quickly the patents for our home inventors, but with the influence of our carefully read and extensively circulated journals, we are enabled to illustrate the intrinsic merits of their patents, and secure a due reward to the inventor, besides serving the public who are more ready to give a fair trial, and adopt a good thing, upon the recommendation of honest and intelligent publishers.

To Obtain a Patent,

well-constructed model is generally first needed, if the invention can well be thus illustrated. It must not exceed 12 inches in length or height. When practicable, a smaller model is even more desirable. Paint or engrave the name of the article, and the name of the inventor, and his address upon it.

Send the model (by express or other reliable conveyance), plainly addressed, to "DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, SAN FRANCISCO." At the same time, send a full description, embodying all the ideas and claims of the inventor respecting the improvement describing the various parts and their operations.

Also send \$15 currency, amount of first fee of the Government. The case will be placed on our regular file, the drawings executed, and the documents made up, and soon sent to the inventor for signing.

As soon as signed and returned to us with the fees then due us, it will be sent straightway to the Patent Office at Washington.

When the invention consists of a new article of manufacture, a medicine, or a new composition, samples of the separated ingredients, sufficient to make the experiment (unless they are of a common and well-known character), and also of the manufactured article itself, must be furnished, with full description of the entire preparation.

For Processes, frequently no model or drawings are necessary. In such case, the applicant has only to send us an exact description, and what is desirable to claim.

For designs no models are necessary. Duplicate drawings are required, and the specifications and other papers should be made up with care and accuracy. In some instances for design patents two photographs, with the negative, answer well instead of drawings.

For further information, send a stamp for our illustrated circular, containing a digest of PATENT LAWS, 112 illustrated mechanical movements, and HINTS AND INSTRUCTIONS regarding the RIGHTS AND PRIVILEGES of inventors and patentees, which will be furnished post paid. Also a copy of NEW PATENT LAW of 1870.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the greatest number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces.—Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

Richardson & Co., Copper Ore Wharves,
SWANSEA.

RICHARDSON & Co. have been for thirty years established in Swansea as Agents for the preparation, Sampling, Assaying, and Sales of Copper, Silver, Gold, Lead, Zinc, and all other Ores and Metals, for which they have extensive Warehouses and Wharves under cover, 1,600 feet of Quay Frontage within the Floating Dock, and the most complete Machinery and Appliances. They are also prepared to make advances against Ores in anticipation of realization, and to guarantee all payments when required. 17v24-1y

Handsomely engraved on stone, colored in counties, and mounted on cloth, showing the Counties, Towns, Rivers, Lakes, Railroads, Mines and Mining Districts throughout the Territory, and all GOVERNMENT SURVEYS made to date. Price, mounted, \$8; Pocket form, \$5. Mailed to any part of the United States, on receipt of price, by A. L. BANCROFT & CO., 721 Market street, San Francisco, Cal., or by B. A. M. FROISETH, Publisher, Salt Lake City, Utah. 10v25-1f

EUCALYPTUS.

The attention of the Medical profession is respectfully called to the following preparation of this new remedial agent. Eucalyptus and its preparations have been found useful in obstinate cases of intermittent and Malarial Fevers, often supplanting the use of Quinine. The paroxysms of Asthma and Catarrh are greatly controlled, and in various Kidney diseases and Catarrh of the Bladder it seems to act like a specific.

FLUID EXTRACT EUCALYPTUS.

This extract represents in a concentrated form the medicinal effect of the leaves of Eucalyptus Globulus.

THE ELIXIR OF EUCALYPTUS.

This compound presents the properties of the leaves in a palatable form and elegant appearance. Dose—One tablespoonful, to be repeated as often as the case demands.

Cigarettes of Eucalyptus Globulus, useful in Asthma. Difficulty of Breathing, Influenza, Etc., Etc. Prepared and sold by JAMES G. STEELE & CO., Chemists and Apothecaries,

No. 521 Montgomery St., between Clay and Commercial, San Francisco. no28

L. SCHUMANN,

PIONEER

Meerscham Pipe Manufacturer,

No. 341 KEARNY STREET,

Between Bush and Pine streets, San Francisco

The first and only Manufactory on the Pacific Coast. MEERSCHAUM MOUNTED WITH SILVER. Meerscham Pipes Bored and Repaired. Amber Mouth-pieces Fitted.

[Special Mention.]
Let Them Come!

We are informed by letter from Capt. J. M. Keeler, of New York, who exhibited the *Eureka Pump* last season in our city and at the State Fair, that a Stock Company, to be known as the Keeler, Hine & Thomas Co., has been organized in New York to manufacture and sell this Pump on our Coast, and that it will hereafter be called after the inventor, as the Government have adopted it for fire and bilge purposes on vessels, calling it the Sluothur Pump.

This Company propose to open a house in San Francisco some time in March, and will also sell Pipe, Hoses, and Brass Fixtures, Ornamental Castings and wrought work in brass and iron; Stable Fixtures, Weather Vanes, Crestings and Rustic Work, Statuary, Figures, Vases and Fountains for Ornamental Grounds; and in fact all the most valuable improvements pertaining to water works, public and private grounds and parks, and claiming the best Pump for hand and windmill power. They also set forth that they will exhibit the best windmill in the world; and they claim to have the best and most powerful Pump for deep mining and for forcing water through towns and cities for ordinary and hydrant purposes, and to serve the immense requirements of irrigation on our Coast.

Capt. Keeler is an old Californian, and seems to understand the needs of the Pacific Coast. He is the Vice-President of this Company, and will come out to take the management of the business.

The main propositions of this Company concern our most vital interests, and we hope they can be fully demonstrated, consequently we bespeak them a hearty welcome and abundant success, and we repeat, let them come.

"PAIN-KILLER."—There can be no necessity, at this late day, for the *Press* to speak in commendatory terms of this remarkable medicine, in order to promote its sale; for it is a medicine that is known and appreciated the wide world through. Whenever we speak of the Pain-Killer, as in the present instance, we do so in behalf of the afflicted, rather than with the view of advancing the interest of its proprietors. For various diseases, such as rheumatism, cholera, cholera-morbus, burns, sprains, bruises, and so on, to the end of the catalogue, we are convinced that there is no remedy before the people equal to Davis' Vegetable "Pain-Killer," and we know that thousands upon thousands entertain the same belief. Certainly, we cannot refer to the history of any medicine which equals that of the Pain-Killer. It was introduced in 1840, and from that time to this its sale, both at home and abroad, has constantly and rapidly increased, and we rejoice at the high reputation it has achieved, because this reputation shows that it has been the means of relieving a vast amount of human suffering. We hope the present proprietors of Davis' Vegetable "Pain-Killer" will long live to enjoy the popularity they have so fairly won.

A CARD.—Mr. Editor.—I beg to inform the public generally, that one Charles O. Milton, who has been exhibiting a fire escape at Woodward's Gardens and other public places, of late, claims that this invention is his. In justice to the right inventor of this device, I beg to inform you that the invention belongs to me in Washington, D. C., in the presence of many and distinguished gentlemen connected with the Patent Office and Public Works Department. Yours, etc., ROBERTSON RUTTER, Sole Inventor. San Francisco, Feb. 25, 1873.

No LIFE INSURANCE COMPANY has a better record or more permanently popular reputation than the CONNECTICUT MUTUAL LIFE INSURANCE CO., J. E. Roberts, 315 California Street, San Francisco, is general agent for this Coast. Send to him for circulars and information of this reliable, first-class company.

NOVEL AND PROLIFIC VARIETY Branching Joint Pop Corn.

[From Pacific Rural Press.]
For CORN.—In our illustration we present a variety that claims the merit of being simply perfect pop-corn; it was raised by Joseph Dimmock, of Windsor, Sonoma County, last year. It is exceedingly prolific, and many stalks produced ears that were above by our engraving. We have tried the popping quality of this corn, and know it to be superior. It matures early.
We have before spoken of the remarkable production, and can vouch for its growth in California, as stated above; but for its success elsewhere we quote the following from Mr. J. J. Johnson, who first propagated it:
"The most productive variety known, producing from EIGHT to TEN EARS ON EACH STALK. Equal to a yield of from 150 to 200 bushels per acre. Although it is strictly speaking, a variety of parching corn, it is adapted to all purposes of common field corn for stock and poultry feeding, etc. It weighs, when shelled, stricken measure, 58 1/2 pounds per bushel. It should be planted in drills three feet apart, putting one kernel to every foot."

Prices, 25 Cents.
For sale, Wholesale and Retail by
E. E. MOORE,
425 Washington St., S. F.

GOOD WORDS

—FOR THE—

PAIN-KILLER.

We can confidently recommend the Pain-Killer.—[Toronto Baptist.]

It is the most effectual remedy we know of for Aches, Pains, flesh wounds, &c.—[St. Johns News, P. Q.]

We advise that every family should have an effective and speedy Pain-Killer.—[Amherst N. S. Gazette.]

Our own experience is that a bottle of Pain-Killer is the best Physician a traveller can have.—[Hamilton Spectator.]

For both internal and external application have found it of great value.—[Chris. Era.]

A medicine no family should be without.—[Montreal Transcript.]

Could hardly keep house without it.—[Ed. Voice.]

Should be kept in every house, in readiness for sudden attacks of sickness.—[Chris. Press.]

No article ever obtained such unbounded popularity.—[Salem Observer.]

One of the most reliable specifics of the age.—[Old North State.]

Its power is wonderful and unequalled in relieving the most severe pain.—[Burlington Sentinel.]

An indispensable article in the medicine chest.—[N. Y. Examiner.]

It will recommend itself to all who use it.—[Georgia Enterprise.]

Is extensively used and sought after as a really useful medicine.—[Journal, St. John, N. B.]

No medicine has acquired such a reputation; it has real merit.—[Newport Daily News.]

One of the most useful medicines; have used it and dispensed it for the past twenty years.—[Rev. Wm. Ward, Assam.]

The most valuable medicine now in use.—[Teun. Organ.]

It is really a valuable medicine, and used by many physicians.—[Boston Traveler.]

We always keep it where we can put our hands on it in the dark, if need be.—[Rev. C. Hubbard, Burmah.]

One of the few articles that are just what they pretend to be.—[Brunswick Telegraph.]

In my mountain travels no medicine is as of universal application as Pain-Killer.—[Rev. M. H. Bixby, Burmah.]

Scorpion Silver Mining Company.—Loca-

tion of Works, Virginia City, Storey County, Nevada. Principal place of business, San Francisco, California. Notice is hereby given, that at a meeting of the Directors of said Company, held on the 5th day of February, 1873, an assessment of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, at No. 523 Kearny street, Room 22, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 12th day of March, 1873, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 26th day of March, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors. WM. H. MARTIN Secretary, Office, 523 Kearny street, Room 22, San Francisco, California.

Mining and Other Companies.

Owing to the time necessary to mail the present large edition of the M. & S. Press, we are obliged to go to press on Thursday evening—which is the very latest hour we can receive advertisements.

Admiral Nelson Tunnel and Mining Com-

pany.—Location of works, Emma Hill, Little Cottonwood Mining District, Salt Lake County, Utah Territory. Principal place of business, in the city of San Francisco, California. Notice is hereby given, that at a meeting of the Board of Directors of said Company, held on the 27th day of January, A. D. 1873, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary of the Company, at his office, No. 539 California street, San Francisco, Cal., by stock upon which said assessment shall remain unpaid on Saturday, the 8th day of March, A. D. 1873, will be delinquent, and will be duly advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 26th day of March, A. D. 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. R. H. SINTON, Secretary, Office, No. 539 California Street, San Francisco.

Eagle Quicksilver Mining Company.—Loca-

tion of works, Santa Barbara County, California. Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the 18th day of January, 1873, an assessment of fifty dollars (\$50) per share was levied upon the capital stock of said Company, payable immediately in gold coin of the United States, to the Secretary at his office, Room 5 and 6, No. 302 Montgomery street, San Francisco, California. Any share upon which said assessment shall remain unpaid on Wednesday, the 13th day of March, 1873, shall be deemed delinquent, and will be duly advertised on Saturday, March 23d, 1873, for sale at public auction, and unless payment shall be made before, will be sold on Monday, the 26th day of March, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees. W. H. WATSON, Secretary, Office, Room 5 and 6, No. 302 Montgomery street, San Francisco, Cal. fe25

OCCIDENTAL FOUNDRY,

137 and 139 First st., near the Gas Works, San Francisco.

STEIGER & BOLAND,

IRON FOUNDERS.

IRON CASTINGS of all descriptions at short notice. All orders punctually executed in time agreed on. Particular attention paid to making superior Shoes and Dies. Among the special castings of this Foundry are the well known CALLAHAN GRATE BAR, of superior merit for burning screenings—all size Bars. STRATTON'S JACK SCREWS, all sizes. Superior compact and effective Horse Powers, Pumps, Agricultural Castings, Ingot Moulds, Assaying and Refining Retorts and Kettles, and a great variety of other and special castings.

STEIGER & BOLAND Proprietors.

Steiger & Boland are the sole Manufacturers of the Improved Hepburn Roller Pan. The patterns having all the improvements to those Pans are at the Occidental Foundry, enabling the Establishment to deliver all pans and parts thereof with uniformity, finished in the best style, and at the lowest possible price. Pan Castings furnished the trade, with liberal facilities for erection, &c. All persons are cautioned against making, selling or using these Pans, except through the authorized agents and manufacturers, viz., Steiger & Boland, of the Occidental Foundry, S. F.

25725-3m

WM. H. HEPBURN.

This Cut represents the Governor with all the improvements. It is simple in its construction and accurate in the regulation of speed, with a positive active trip valve attached, a preventive against all accidents liable to occur from the parting of the Governor belt or any other cause that would prevent the working of the Governor, and is so arranged that the speed of the Engine can be readily adjusted while in motion, without change of Pulleys.

DESCRIPTION.

The Valve Stem is divided into two parts, viz: the upper and lower Stem; the upper Stem being connected at the top with the sliding Sleeve to which the Spring and Gear is attached; the lower Stem is attached to the Valve by an adjustable screw and stirrup by which the Valve is adjusted by a thumb screw at the upper end. The upper and lower Stems are connected together by a Ketch on the lower Stem, which fits into a turned Groove on the lower end of the upper Stem, and is disconnected by the end of the Ketch coming against the sleeve through which the upper Stem passes, allowing the Valve to drop, which immediately shuts off the Steam. To connect the Stems turn the thumb-wheel half round, so that the Ketch may pass into the recess in the Sleeve. After starting engine, turn the Ketch half round and secure with Spring on front.

RECOMMENDATION.

St. PATRICK MILL, Placer Co., Feb. 10, 1873.

JOSHUA HENDY, ESQ., SAN FRANCISCO.
Dear Sir: We, the undersigned, take pleasure in giving you the following testimonial as to the merits of the Hendy Governor, which we ordered from you about four months ago. Though more than pleased with its workings at first, we deferred writing until we had tested it thoroughly.

Our engine is 12½ hp (carrying 70 lbs. of steam), driving 15 stamps, 12½ lbs. each; 1 Wheeler Pan, 1 Knox Pan, 6 Hendy Concentrators. The discarded Governor was the common "Arm and Ball Governor;" it giving but poor satisfaction, we decided to try the "HENDY," and are pleased to report in its favor for the following reasons:

1st. It saves Fuel. Previous to attaching your Governor we were burning 3½ cords of wood per 24 hours. We now consume but 2½ cords doing the same work.

2d. For safety. The "trip" saved us from an expensive smash up but a few days ago, during the temporary absence of our engineer. The Governor belt ran off the Pulleys. Your little automatic trip worked like a charm, and but one or two revolutions was the result, and no damage. Had we been using any other Governor, the probability is that we would not have had a whole cam in the mill.

3d. It is a PERFECT GOVERNOR. We can turn off the Wheeler Pan and hang up one-third of our stamp, without any perceptible change in speed.

4th. THE ADJUSTMENT for regulating the speed without increasing or reducing the size of our Governor pulley, is admirable, and as easy as setting a clock.

5th. It is simple and yet able to get out of order, or requiring more than ordinary care.

Yours res. truly,

J. S. H. CROSSMAN, Supt.
(Signed by request.) GEO. H. BARNEY, Chief Eng'r.

BURLEIGH

ROCK DRILLS

—AND—

Air Compressors.

The Burleigh Rock Drills, which have stood the test of five years' constant use at the Hoosac Tunnel, and which are now in use in nearly every State in the Union, as well as in Europe and South America, are unequalled in efficiency and economy by any other Drilling Machine. They are of various sizes, and equally well adapted to Tunneling, Shafting, Open Cut or Quarrying, and will drill six to ten inches per minute in granite. They are driven by steam above ground. The Burleigh Air Compressor is the best engine yet devised for furnishing the "air motor" for the many purposes to which it is now being used.

They are to be used on the St. Gothard Tunnel, Switzerland; Tunnel 13 miles long. We refer to the following gentlemen and works:

Gen. Newton, U. S. A.....Hell Gate Tunnel, L. I.
Mess. Shanley.....Hoosac Tunnel, Mass.
J. Dutton Steele.....Nequehoning Tunnel, Pa.

BROWN'S PATENT LAMP.

One of these Lamps, when placed at a distance of 200
feet from the bank, will light up a bank surface 260 feet
in length and 160 feet high, and to a much better ad-
vantage than any other light heretofore tried, and at an
expense not to exceed five cents per hour. Lamps
furnished at short notice.

[Letter of Recommendation.

Me, C. B. BROWN—Sir: Your Patent Lamp for light-
ing hydraulic mines, which you sold to me in December
last, has given entire satisfaction, and far exceeds my
expectations, and I think it the best and cheapest light
ever used to light mining claims by night, and am sat-
isfied that I have saved three hundred dollars by the
use of it in the last mining season over pitch or any
other light of the same brilliancy; and I will also say
that if I could not get another lamp, five hundred dol-
lars would not buy it. Yours,
W. D. APLIN.

HALLIDIE'S
Patent Endless Wire Ropeway.
Covered by Numerous U. S. Patents.

IMPORTANT TO
Mining Companies, Civil Engineers, Contractors, Etc.

The system of transporting material, such as Ores, from the mine to the mill, Earths for embankments, Rock from quarries, etc., by means of steel wire rope, has been well tested and found more economical, advantageous and reliable than any other method of transportation; and to the annexed certificates in connection therewith I beg to call the attention of those interested:

EUREKA, Nevada, July 10, 1872.
T. M. MARTIN - My dear sir: On your leaving for San Francisco, it gives me great pleasure to hand you my written acceptance of the HALLIDIE TRAMWAY put up by you upon our mine in Freshburg.

It is a perfect success, discharging ten tons of ore per hour with two men's labor. It is perfectly simple in construction, and, as far as I can judge, there is nothing about it to ever get out of order - nothing to wear out. While ours requires but about two thousand five hundred feet of wire rope, I can see no reason why the line could not be extended almost indefinitely with equally happy results. Again, the carrying capacity might be doubled or quadrupled if desired. After several weeks trial upon our mine, the unanimous verdict of all who have seen it is a complete, unquestioned success. If this can be of any service to you, use it in any way you think proper. Very respectfully, O. C. GOODWIN.

EMMA HILL CONSOLIDATED MINING CO.,
Little Cottonwood, Utah.
Superintendent's Office, Sept. 23, 1872.
T. M. MARTIN, Esq. - Sir: The Ropeway constructed by you (HALLIDIE'S PATENT) for the Emma Hill Consolidated Mining Company, has been built in a most substantial and workmanlike manner, and is at this time in splendid working condition. I most cheerfully accept the work for the Company, and recommend it to others, weighing a sure and speedy transit for ores over places impracticable for wagon roads, etc. Respectfully,
J. W. COLBATH, Superintendent.

"The Vallejo works smoothly with the elevated wire tramway, which carries its load of ore as lightly and easily as if there was no winter or snow in the world."
"Whatever the objections to wire tramways may be on account of their cost, I have seen nothing yet that even approaches them in the facilities they afford for moving ore at all seasons of the year." - Correspondent Utah Mining Journal, Alta, Jan. 8, 1873.

The Vallejo Ropeway.
The Vallejo Tunnel Company's Tramway in Little Cottonwood, built on the HALLIDIE PATENTED PLAN, is a complete success. It is between 2,300 and 2,400 feet in length, and is supported by thirteen stations. The fall in this distance is about 600 feet, and the wire rope, which is three-fourths of an inch in diameter, will safely and easily deliver one hundred tons in six hours. The machinery is automatic, loading and unloading the trucks or chutes. About one ton and a half can be sent down at one time. The stations are about two hundred feet apart, and the entire apparatus is strong and safe. As the wire rope is elevated about forty feet above the surface of the hill, the Tramway can be worked all winter long, without the slightest trouble. - Utah Mining Journal, Salt Lake, Sept. 23, 1872.
Mining Companies and others desiring to negotiate for the erection of this system of Ropeway, can communicate with me personally, or through Postoffice Box 964.

A. S. HALLIDIE, Patentee,
112 and 114 California Street, SAN FRANCISCO.
WIRE ROPE

Number 10.

Economy of Fuel—Using Steam Expansively.

Much has been said and written on using steam expansively, and opinions vary greatly as to whether it is economical or not to do so. We saw this week at the establishment of the Kimball carriage manufacturing company, a practical solution, in dollars and cents, of this question. The engine used to drive the machinery has a 12-inch cylinder with 24-inch stroke. It has been running since it was erected, without any cut-off, and required in addition to the sawdust, shavings, and waste wood of the factory, \$30 worth of coal per week for fuel. On the first of January, without making any other change in the engine, a common lap-valve cut-off was put on, since which time the coal bill of \$30 per week has been entirely dispensed with. Now, nothing but saw-dust and shavings are used, with a little tan bark to keep the saw-dust from flying, and even the waste pieces are saved and used for domestic purposes. The fireman is not allowed to feed with these pieces. The cut-off is adjustable at pleasure but is generally set to cut off at about a quarter of the stroke. The average pressure of steam carried is 80 pounds, about five pounds higher than was carried previously.

This example is a good demonstration of the economy of using steam expansively and is a practical illustration of a question which has been written about many years. Some judgment of course, has to be used in putting on a cut-off and in operating it. Many people have tried using them, and being unsuccessful, have condemned them. The engineer says that the wear of the cylinder and packing rings in this engine is very different from what it was before. The cylinder has acquired a perfectly glossy surface since the steam has been used expansively, while before it had a granulated appearance. The engine runs much easier and to appearance will do as much work when cut off at one-third of the stroke as it does when running full stroke; of course, in the latter instance, using three times the amount of steam. The expense of putting on the cut-off was about \$250, and as the saving is reckoned at \$30 per week, it has paid for itself in two months. Captain Tyler, who has charge of the machinery at the factory, expresses himself well pleased with the way the engine runs and the economical result, as of course do the proprietors.

EXPECTED LABOR STRIKES.—A dispatch dated New York March 4th makes the following statement: "The Tribune is authority for the following statement that another series of labor strikes, similar to those of last year, are shortly to be made. The battle will be renewed late in April or early in May. Trade organizations are now making extraordinary efforts to gain recruits, as so to move with a solid front when the signal for revolt is given. Employers, however, are prepared, and have evaded large contracts. They will co-operate in making a general defense. Trade unions are now much excited over the coming struggle. The Tribune deprecates the renewal of last year's strikes, and points to the failures and loss to both capital and labor interests, and to the whole community, as reason why they should not recur."

THE WELSH STRIKE.—The iron workers of Merthyr-Tydvil have signified their willingness to resume work at the old rates of wages until the end of March, if an advance of five per cent, is guaranteed from April 1st. This action may end the long strike.

The Pulverizing Barrel.

[Written for MINING AND SCIENTIFIC PRESS by A. Blatchly.]

The revolving iron barrel was first used in this country for cleaning sand from small iron castings and for polishing chains. It was made of different sizes, from two feet in diameter and two feet long, to three feet and a half in diameter and six feet long. The heads were usually of cast iron of sufficient thickness on their peripheries to receive bolts for securing the staves, which were made of cast or wrought iron. Cast iron staves had flanges on the outside to strengthen them when of large size. They were bolted on the heads in such a manner as to leave a small space between them for the escape of the sand as fast as it became detached from the castings, which prevented their sharp corners from being worn away by the sand.

When the barrel was used to polish chains the staves were placed close together so as to retain the sand or emery employed in polishing from escaping from the barrel. In this manner the polishing was rapidly effected, and

out, a new set could be put in place in a short time and the vessel would be as good as new.

These vessels were charged with from six to twelve hundred pounds of iron balls and one thousand pounds of ore, but the feed and discharge of ore was continuous. After the ore was ground it was bolted and that which was not fine enough was returned into the barrel and re-ground.

These barrels were four feet in length and in diameter, and would reduce from six to ten tons per day, the ore being previously reduced in a jaw crusher. The wear of iron in the barrels and on the balls per ton of ore reduced was about the same as in a stamp mill.

In the next will be a description and cut of Paul's Barrel, and a consideration of the principles involved in its operation.

Steven's Oxy-Hydrogen Furnace.

An ore smelting furnace of Levi Steven's patent has been erected at the corner of Main and Harrison streets in this city, and was tried this week. We gave a complete description of this furnace, with a view of it in the MINING AND SCIENTIFIC PRESS of December 7th, 1872, so it is not necessary to go into particulars again. It is intended to economize fuel, and

is running by means of an opening in front, and it can be run night and day for some time without cleaning out. The fuel being ejected into the furnace in a liquid or gaseous form there is very little residue, and what does form, remains on a shelf in front of the burners, from where it can easily be removed. For localities where fuel is scarce and high, this furnace will be extremely useful. Several of them will be put up in different parts of the coast before long, and we will endeavor to obtain the details of their working. This furnace will be especially applicable in the Inyo county mines, for instance, where there is an abundance of asphaltum, and where coal is scarce. Mr. Stevens will no doubt, when his furnace is fully completed, give a more extended trial of its properties, the particulars of which we will lay before our readers.

"HILLS LOOK GREEN AFAR OFF."—It is reported in Salt Lake City that parties there have had an agent out on a prospecting tour in French Guiana, who has returned corroborating accounts of the fabulous richness of the gold mines there. It is said a vessel has been purchased and a grand move is to be made in that direction soon. The rocks of British Guiana, which is the western portion of the territory, are granite porphyry and sandstone. Traces of iron have been found there, but none of the precious metals. French Guiana has the same general characteristics with a fertile soil and salubrious climate. The mountain chains run from east to west, and are almost wholly granite, and in the center of these calmly rise from 12,000 to 15,000 feet above sea-level. There are 20 rivers in the territory, and the gold may have been found there, if it has been found at all. There are plenty of good mines in our own State, which can be worked with profit, without miners getting up an "excitement" to go to such a distant locality for the yellow dust. A company was incorporated in this city this week to mine in the Island of Papua or New Guinea, and that may be the country to which the dispatch referred.

NARROW GAUGE RAILROADS.—The following gentlemen have been elected Directors of the San Joaquin Valley and Vernalis Narrow Gauge Railroad: E. F. Northam, W. B. Boura, G. F. Smith, C. Grattan, R. C. Sargent, A. Leitch, C. M. Blair, H. C. Dallas, R. C. Hyde, E. Jacobs and S. Sweet. It is now highly probable that this road will be completed at an early day and will not only benefit Stockton and Vernalis but all property within 25 or 30 miles of the road.

The engineers are now making estimates of the cost of construction of the Martinez and San Ramon Valley narrow gauge road and will shortly report.

Work on the Marin County narrow gauge road is progressing rapidly. About 300 men are now employed.

ENGLISH MINES.—Forty-six mines in Devon and Cornwall paid out in 123 dividends last year the sum of £275,450. The largest amount paid by any one mine was £48,000 and the smallest £121. This does not make much of a showing for so many mines and so many dividends, as it only foots about \$1,372,000. However, this is only from two counties.

MONTANA ORE SHIPMENTS.—Two hundred tons of silver ore were purchased at Bannock City Montana, on the 15th of February, to be shipped to Swansea for reduction. From \$30 to fifty per ton were paid for various lots,

VIEW OF PULVERIZING BARREL.

when fine emery was employed the polish was very smooth and bright. To charge and discharge, an opening was made in the side of the barrel and closed as shown in the cut of the barrel at c by an iron plate.

One of the first applications, if not the first, of this barrel to pulverizing ores was made in Colorado, when it was called a Bell Pulverizer, from a large number of balls which were charged in the barrel with the ore. B represents this barrel; D is a head showing how the staves are secured into it.

The staves are made of cast iron of the same degree of hardness as shoes and dies for a stamp mill. They are from two to three inches wide and one inch thick, cast with a slight projection on each side at the ends, so as to leave an opening between the staves for the escape of the ore as soon as it is ground sufficiently fine.

In the first barrels constructed, from four to six staves, much thicker than the rest, were set at equal distances from each other, which projected three or four inches further into the barrel than the other staves, making the inside of the barrel with projecting ledges so that as the barrel revolved the ore would be properly jolted. This device though excellent in theory was unfortunate in practice, as the barrel required much more power to drive it, and failed to grind it as fast as when all of the staves were of equal thickness and the inside of the barrel was smooth.

The barrel was held together by rods e, e, passing through the heads and secured by screws and nuts. When the staves were worn

it run with coal tar or asphaltum and superheated steam. The fuel is fed through a pipe and is blown in by the steam. The patentee claims that he utilizes the elements of the water by decomposing it, to aid combustion. At all events he makes a very hot fire, which seems to answer all purposes. The operation is very simple and the heat is under ready control, being reduced or augmented by simply turning on more or less steam; the supply of fuel can of course be controlled.

The furnace in question is not entirely completed, but it ran well enough to demonstrate its applicability for the purpose. The ore is fed from hoppers into a desulphurizer in which a shaft revolves, having upon it paddles, which convey it into the furnace. In this instance the ore was fed in without being desulphurized as the shaft was not ready to be run. The ore used was of low grade argentiferous galena. The fire was started in the furnace at half-past ten, and at half-past twelve the bullion was drawn out—two hours being consumed in thoroughly heating the furnace and reducing the ore. The contents was in a perfectly liquid form, and the ore as it dropped from above seemed to be immediately reduced to a plastic state as soon as it touched the inclined shelf at the back of the furnace. From there it gradually ran down to the bottom where it was completely liquified.

The slag is taken from the furnace while it

Resources of Utah.—Some of Its Principal Mines.—Continued.

The Silver Glimpse Mine,

In American Fork mining district, is owned by Messrs. John Tismna and others, of Salt Lake City. The mine was discovered in the month of October, 1870. It is situated on Silver Glances Hill. The extensive workings have developed an immense vein of ore, encased in well-defined walls, having an average width of six feet. The course of the vein is southeast and northwest, and it is traced and opened for a distance of over 700 feet, thereby establishing the vast extent, intrinsic value and permanency of the property. Several hundred tons of ore were taken out during the developments which are now laying on the dump. The work done embraces four tunnels and two inclines, the combined length of which is over 500 feet.

The character of the ore is chlorides and carbonates with silver glance and native silver. The average assay value is about \$100 to the ton. Some assays of ore from this mine have run as high as \$6,410. As a matter of interest we append a list of assays that have been made with their results:

June 6, 1871.....	\$ 64.10
Oct. 29, 1871.....	4,845.59
Aug. 7, 1871.....	2,276.70
June 24, 1871.....	2,174.71
" " ".....	1,952.80
" " ".....	1,436.60
Nov. 24, 1871.....	
Average of 19 assays.....	440.08

The Amador Mine,

In Little Cottonwood, is west of Emma Hill, and at the head of Superior Gulch. This mine, although not much known, presents a very promising appearance. The vein where exposed in the workings is three feet thick and has all the indications of being a true fissure. The ore is high-grade, free milling, and carrying silver and gold with very little lead. Some eminent Eastern capitalists are investigating the merits of this and some adjacent mines with a view of purchase. The high standing and position of the gentlemen in question is such as to warrant the supposition that there is considerable value attached to the property.

The Vulcan Mine,

Situated about a mile from the city of Stockton, Rush Valley District, in the lower mineral belt, is one of the most promising mines in that neighborhood. The vein has a width of three feet and is distinctly traceable through all present developments. The ore is of very easy reduction, carrying a high percentage of lead, and is found to be a splendid flux in combination with the high-grade ores of Dry Cañon. The owners are actively pushing work upon the property. If present appearances are borne out in future developments, this mine will rank among the prominent mines of the Territory. The character of ore, Carbonate and Galena, assaying on an average, \$50 in silver and 40 per cent. in lead per ton.

The Chicago Mine of Tinic

Is situated about three-quarters of a mile from Silver City, Tintic Mining District. It is on the line of the great mineral belt running through the District. The lode is a well-defined fissure vein in a granite formation. The surface indications are exceedingly favorable, equalling many others in the District, and rich and regular body of ore having been developed. The work consists of a shaft 106 feet deep. About 100 feet southward from the shaft is a cut 26 feet deep, and a shaft has been sunk from it on the vein to a depth of 30 feet. From the bottom of the shaft a drift is run southward for 70 feet and northward for 100 feet, both worked on the lode and exhibiting a good body of ore and a regular foot wall at a depth of 100 feet. In connection with the works is a deep tunnel to facilitate operations. It is opened about 80 feet and will soon reach the lode. The character of the ores is carbonates, sulphurates and chlorides of silver, with a small percentage of lead. They are very high grade, as proved by assay. The surroundings of the mine are very favorable, both as regards location and facilities of transportation, besides being in close proximity to a mill now being erected on Tanner's ranch.

[ADDENDA TO FURNACES.]

The Davenport Silver Mining Co's.

Furnace erected in the fall of 1872 are situated at the mouth of Little Cottonwood Cañon, and consists of two cupola blast furnaces of a capacity of ten tons of bullion each per day. The motive power for the machinery is water, obtained from Little Cottonwood creek. Each furnace is provided with a separate blower which possesses many advantages in smelting. The buildings are very large and well ventilated—a feature sometimes neglected in the construction of smelting works. The ores used at these works are chiefly from the company's mines—the Davenport, Matilda, etc., of Little Cottonwood Cañon. The charcoal used as fuel is from Truckee, California and iron ore for flux from Rawlins, Wyoming Territory. The general management is vested in John H. Ely of this city and Jay H. Wooley, Superintendent, under whose supervision the works were erected. The plans were made by J. C. Cameron, Jr., and the mason work under contract by Evans and Morris of this city.

[ADDENDA TO BINGHAM CANON.]

In addition to the mines already mentioned the following should be noticed:

The Grand Cross is about one mile and a half

from Bingham City. The works consist of a shaft 22 feet and a tunnel 104 feet. The surface indications and the ore exhibited in the works, give promise of very favorable results. The Life Pine has a shaft down 101 feet, bringing to light a fine body of ore.

The Silver Shield has a shaft 90 feet deep and the appearances so far are very promising. *Salt Lake Tribune.*

The Metallurgy of Gold and Silver.

The metallurgy of precious metals does not hold that position in the scientific schools of this country that it should. This is a fact that is patent to any one, who, after passing through the best of them ventures upon the business of milling or smelting even with some practical experience in the general working of ores. The reason is probably to be found in the fact that the industry is comparatively a new one to Americans, and consequently its importance not fully comprehended. The west is yet young, and must for some years to come draw upon the older states for its guides in science, and it will prove an injury to technological and mining schools if they fail at this point.

Without presuming that the mines of the Rocky Mountains and Pacific Slope will prove to be the

The Greatest Wealth of the Country,

Or without even ranking them as of so great importance as the iron or coal deposits, it is certain that they will be worked with greater zeal and energy, simply because they are precious, and judging from their yield in past years will constitute a leading industry in the future. It will also be the case that a very large percentage of the yield of the ores when properly treated will be base metals, the market for which is constantly enlarging. Even at present all the silver producing Territories are shipping away more or less lead, and considerable copper in the form of matte is annually produced. Only the difficulties in the way of a cheap method of smelting retard the growth of base metal production, while the unlimited quantities of these ores, associated with those of gold and silver, are almost a positive guarantee of the future importance of the business.

Were all the

Gold and Silver of the West

Washed from the sand of its ancient rivers, or taken from the veins of free milling ore, there would certainly be some reason for placing the metallurgy of these metals at the foot of the list in importance, and the whole ground of their working might be covered by the elaboration of a few simple processes. This however is not the case. The palmy days of the rocker and long-tom are rapidly passing away, and raw amalgamation can only be adopted with a small proportion of ores now mined. Especially is this true in Colorado. Its gold does not save well in stamps and the majority of its silver ores are refractory in the extreme. The old processes of Europe will not answer without considerable modifications, not only on account of the higher rates of labor and material, but because a class of deposits are to be handled differing from most of theirs. Outside, but little is heard of the innumerable experiments and failures, while here everything is in earnest, and while the scientific men of the east are studying, and modelling after the old methods of the ancients, almost a new science is springing up in the mining west, in answer to the needs of the country.

In Colorado we are having the privilege of solving some of the most

Difficult Problems of Metallurgy,

And to the honor of the Territory it can be said that the numerous failures that have occurred, have not discouraged her mill-men, nor dampened their energy. We doubt if any other district on the continent can afford a more complete and varied study for the metallurgist. Its gold is found nearly always associated with iron and copper, the latter in quantities varying from three to twenty per cent. Its silver is in a majority of cases carried in zinc or lead ores, and often with an admixture of antimony and arsenic. Were only one or two of these present the difficulties would not be so great. As it is however a very small number of mines yield rock that can be properly handled in any other way than by a long and complicated process.

We have been forced therefore to experiment largely, and as experiment always necessitates some failure, the growth of the country has been retarded, and the investment of foreign capital checked and discouraged in exact proportion. The working of our ores, necessitating as it does a treatment also for the most valuable base metals, and a careful regard for those thieves of gold and silver, zinc, arsenic and antimony, is no mean study, and requires by far more skill and knowledge than is needed in iron and steel working. An acquaintance with the standard processes in use abroad is not sufficient for the successful metallurgist here, though of course the main principles of treatment are identical. A history of the mining districts of the west will show that American inventions and improvements in many cases are superseding foreign ones, and succeeding where they have failed.—*Colorado Mining Review.*

African Gold Mines.

A correspondent of the Springfield *Republican* sends an extract from a letter just received from a friend in the Natal colony, South Africa, whose information in regard to what is going on in that part of the world is reliable. It appears that the Tatin gold diggings, which attracted so much attention a few years ago, are thrown into the shade by the recent discoveries of the precious metal in the Transvaal (Dutch Republic), which is not far from Port Natal. The Tatin fields are at least 1,500 miles from this seaport: "There is a probability of the Marabasiad gold fields turning out a success. One reef is extremely rich, giving from \$70 to \$80 per ton of quartz. There are now some hundreds of men digging for alluvial gold, and they find it, although not in large quantities. In my last letter from there it was reported that one man had obtained an nugget of over half an ounce. Others have found very nice gold of about the size of barley-corn. Mr. Button, a scientific and enterprising Englishman, has formed a company in London, with a capital of £100,000, to work this reef. The new President, Mr. Burgess, from the Cape of Good Hope, has been to these fields, and proclaimed the whole country open to the world for digging purposes, on the payment of ten shillings for a license. (Quite accommodating this on the part of the Dutch.) Diamond digging becoming more difficult and expensive, many are leaving there and going after the gold. The diamond region has been formed into a separate State or Colony, with its own Government and Legislature, and with the control and expenditure of its own revenue. There now seems every probability that railways through the Natal Colony will soon be commenced. Surveys have been made. The first will be constructed along the coast to accommodate the sugar planters and cotton growers. Labor is at present our great want. It is both dear and scarce. Every native man asks 12 or 13 shillings per month. (Cheap enough, we Yankees would say.) Food is also very dear. Indian meal selling at 28s. per bag. Horses and mules are in many cases superseding oxen on the sugar estates. The mules are imported from South America."

American vs. British Mines.

The leading London papers, especially the *Times*, have been of late so severe in their denunciations of foreign mining securities, particularly American ones, that some facts derived from their principal mining authority, the *London Mining Journal*, may be of interest. During the year 1872 the British and foreign dividend-paying mines, in the London market, paid in dividends a total of £972,135 or \$4,860,675. Of British paying mines there are sixty-four; of foreign twenty-six. Yet the twenty-six foreign mines paid more in dividends than the sixty-four British mines. Utah alone in 1872 paid one-fourth of the total amount of dividends, both British and foreign. Of the twenty-six foreign mines, the twelve American paid over two-thirds of the dividends therefrom. Of the ninety-one foreign mines, thirty-five are quoted as dividend-paying (twenty-six only paid in 1872), equivalent to nearly forty per centum of the whole. Of the three-hundred and twenty-nine British mines, seventy-five only are quoted as dividend-paying (sixty-four only paid in 1872), or less than twenty-five per centum of the whole pay.

One American mine, on the borders of Utah, though in Nevada, the Raymond & Ely, paid almost as much as all the British mines put together, and nearly fifty per centum of all the mines on the London list, paying 69 per centum on its capital stock.

Surely American mines are good for something. Yet after perusing the British papers, one might be led to believe there was not a good mine in all America.

PLUMAS COUNTY MINES.—Of the mining outlook in Plumas county, the *Quincy National* says: "The prospect is that more money will be taken from our mines during the year of 1873, than for any previous year for a decade. A large amount of outside capital was invested in Plumas county gravel diggings last summer, and that capital will be returned to the fortunate owners with ten-fold interest. The good results from the investment of this capital will lead other capitalists to look this way, and in a very short time the county of Plumas will be ahead of any county in the State for extensive mining operations. This is no idle boast. The undeveloped resources of the county are immense, capital has already commenced the work of development, and more 'solid men' are coming. A feeling of security has taken the place of distrust, and one and all join in a hopeful prediction of the 'good time coming.'"

PACIFIC PORTS.—Complaints have been made to the Treasury Department that American Consuls at Valparaiso and ports of China are unable to furnish shipping masters with proper charts of the American Pacific ports, and as a consequence, vessels approaching these ports run great risk in navigation. Secretary Boutwell has directed steps to be taken to ascertain if the facts are as stated, and, if so, what remedy is necessary.

The annual pig iron production of the world is about 19,000,000 tons.

Plumbago Mines.

Plumbago, or graphite, is found in crystalline rocks, especially in gneiss, mica slate, and granular limestone, also in granite and argillite, and rarely in greenstone. Its principal English locality is at Borrowdale in Cumberland. In some years the net produce of the six weeks' annual working of the mine has amounted to £40,000. In the United States graphite occurs in large masses in veins in gneiss at Sturbridge, Mass. It is also found in Vermont, Pennsylvania, North and South Carolina, and New York. For the manufacture of pencils the granular graphite is preferred, and it is this character of the Borrowdale graphite which has rendered it so valuable. At Sturbridge, Mass., it is rather coarsely granular and foliated, and has been extensively worked; the mine yields annually about thirty tons of graphite. The mines of New York, Vermont, and North Carolina are also worked; and that of Ashford, Ct., formerly afforded a large amount of plumbago, though now the works are suspended. In addition to being used in the manufacture of pencils, graphite is extensively employed for diminishing the friction of machinery; also for the manufacture of crucibles and furnaces, and as a wash for giving a gloss to iron stoves and railings. For crucibles it is mixed with half its weight of clay. The composition of the mineral is 90 to 96 per cent. of carbon, with the rest iron. It is often called carburetted iron, but it is not a chemical compound. It is infusible before the blowpipe, both alone and with re-agents, and it is not acted upon by acids.

These being the properties of graphite, it is natural that it should be constantly increasing in demand, but for some time past the supply has wonderfully fallen off. The Cumberland mines, on which we depended it may be said for centuries for the supply of plumbago, have, it is well known, been all but worked out, the best quality entirely so, and with all the resources of modern chemistry and scientific appliances the market has been supplied with an inferior material to that produced (at an enhanced price) when the mines were in their palmy days. It is, therefore, a matter of public importance that new sources of supply should be opened up, and if the private view of the ore at the offices of Mr. Harvey, St. Clement's House, Clement's-lane, is to be depended upon, an almost inexhaustible supply of the richest quality has been discovered in Canada, which only needs capital and the requisite machinery to satisfy the public wants of this country and the United States, and at the same time to return large profits to those who embark in the undertaking. The property in question is situated near the village of Buckingham, on the River De Lièvre, a tributary of the Ottawa.

The price offered for plumbago for crucible purposes is now about 6d. per lb., in consequence of the great scarcity. For professional and artistic purposes, of course, the finer quality would bear a proportionate price. If the prospects opened out by the discovery of these mines—in connection with facilities for transit by rail and water carriage—are realized the mines will become most valuable to the public and to their proprietors. The largest and purest specimens are to be placed permanently in the School of Mines.

Quicksilver in Napa and Vallejo.

Since the late rich developments in the Summit quicksilver mine, seventeen miles north of Napa City, J. Perschbaker, the owner, has entered into a contract with forty Mexican miners who formerly worked in the quicksilver mines at New Almaden, to go to work, and as the mine is developed and the work requires them, he has arranged to increase the number to 150. The Mexicans are so well pleased with the developments already made and richness of the mine, that they have contracted to go to work on a percentage of the ore taken out.

The Vallejo quicksilver mines can now be claimed as a success, according to the *Vallejo Chronicle*, as a large body of paying ore has been developed, and the furnaces are being run to a profit to the owners of the mines. A party of Vallejo gentlemen visited the mines yesterday—explored the shafts, tunnels, drifts, etc., inspected the furnaces, and came back, well pleased with what they saw. The *Chronicle*, some two or three months since, mentioned the discovery of apparently a large, well-defined and paying body of ore. Since that time Mr. Neat has developed the ledge for a distance of thirty feet or more, and there is no prospect of its giving out at that point, and as a matter of course, Neat feels highly elated with the success which has at last attended his efforts in quicksilver mining. They are experiencing some inconvenience in not being able to haul lumber to the mines from town now on account of the bad roads. The lumber is wanted to timber up the excavations in the mine. Work on the large, eleven-ton furnace had to be suspended also on account of not being able to get bricks to the ground. The small furnace is running regularly producing about a flask of metal per day, which is worth from \$60 to \$65. Mr. Neat shipped eight flasks of quicksilver to the city last week. Ten men are now employed at the mines.

MILLS SHUT DOWN.—The extreme scarcity of fuel on the Comstock has had the effect of causing Parke & Bowie's tailings mill and several other mills on Six and Seven Mile Cañons to shut down temporarily.

SCIENTIFIC PROGRESS.

Do Plants Exhale Carbonic Acid?

Plants have commonly been thought to differ from animals in the gases which they secrete; the animals parting with carbonic acid, while the plant gave out oxygen. Dr. J. C. Draper, of New York, however, maintains that all living things, whether animal or plant, absorb oxygen and give out carbonic acid; and that the life of the plant is one continuous drinking in of oxygen gas. Having grown plants similarly nourished in the dark and in sunlight, he found that all the same parts were produced in both cases almost at the same times, and that the slightly slower evolution of the series grown in the dark is marked by a slightly smaller weight, while the same plant measured by night and by day grows slightly faster in darkness than in sunlight. The roots of plants grown under both circumstances throw out the same kind of excrement. Therefore, as the evolution and weight and root-secretion agree, he urges that the carbonic acid has been in both cases thrown off as a consequence of growth, and has never been absorbed by the roots and then given out as vapor from the leaves. In conifers and fungi, which, like seedlings grown in the dark, never give out oxygen, he appears to think that the carbonic acid they seem to give off is really only the carbon of the air left around the plant as a consequence of the rapidity with which the oxygen is absorbed; and when plants are producing their flowers and seeds, the rate at which they seem to part with carbonic acid is greater than with many animals at any time. Oxygen is given off only from the green parts of plants and trees—the leaves, twigs and young shoots; and only when the sunlight is falling on the leaves. Dr. Draper's argument might have been made even more convincing if he had availed himself of Boussingault's experiments, which showed that carbonic acid is decomposed day and night, by green leaves, in the ratio of one part by night to about sixteen parts by day.

Are We Witnessing the Formation of New Suns?

Some interesting observations have recently been made in regard to the colored stars about *Kappa Crucis*. Mr. H. C. Russell, of the Sydney Observatory sends to *Nature* an account of some observations which he has made in that portion of the heavens, and ventures the assertion that astronomers will gain fresh knowledge, especially with regard to the Nebular theory, by careful examinations of the phenomena developed in the direction of that beautiful cluster of stars.

Mr. Russell holds that it is beyond all question that, from some cause, there has, as in the direction of *eta Argus*, been recently developed a considerable increase of brilliancy about *Kappa Crucis*; also that there has been not only there, but in other directions in the heavens, a sensible amount of "clearing up" within the last twenty-five years. In other words that the process of the formation of new systems of stars is actually going on, before the eyes of the astronomer; that suns, by careful observations, may be detected in all stages of progress from the greatest nebulousity, "without form and void," to the finished sun, whatever that may be.

It is in this view, Mr. Russell thinks, we may find a rational explanation of the appearance of new stars in and about *Kappa Crucis*. But, whether we admit this or not, one thing is certain; we are not yet prepared to say, with certainty, that such changes are not going on in space, as will suffice for a full explanation of the undoubted appearance of the small new stars above alluded to, if not of the greater changes about *eta Argus*.

THE SILBER LIGHT.—An English inventor, a Mr. Silber, has lately made various improvements in oil lighting, to some of which the *London Times* of a late date refers in favorable terms. Among other lamps to which Mr. Silber has applied his principle are the side and mast-head lights used on ships. He has perfected a covering for these lanterns which, while permitting the free outward passage of heated air from the flame, is completely impenetrable to water washing over it. Waves breaking over side lights so constructed would have no power to extinguish the flame. Satisfactory experiments made with these lamps have amply proved their serviceableness. The principle of construction of these ship lanterns is analogous to that adopted to afford protection against currents of air in the case of street lamps and railway roof lamps. For domestic uses Mr. Silber has also made Moderator and Argand table-lamps, burning colza oil. Tests have shown that lamps constructed on this principle for the same consumption of oil will give 40 or 50 per cent. increase of light over those of ordinary construction.

Solar Flames—A Fearful Possibility.

In the course of a lecture on solar phenomena, delivered on Thursday Evening by Prof. Draper, before the University of New York, the speaker said: "There is one reflection connected with these solar eruptions that has a dire interest for us. If it be true, and there seems to be no doubt about the fact, that these streams of intensely heated hydrogen can be ejected from the body of the sun with a velocity which, if it endured, would bring that breath of fire to our earth in a few hours, what would be the effect of an eruption on a larger scale? What would happen to men and animals if an explosion as general as that in T. Cononae Borealis took place in our sun? In May, 1866, that star, which is usually invisible to the naked eye, suddenly flamed up till it was as bright as a star of the second magnitude. When examined by Miller and Huggins it was found to be enveloped by a prodigious atmosphere. In a few days it dwindled away and sank to its former insignificance.

But what must have been the fate of animated beings on the surrounding planets, if any such there were? They were undoubtedly consumed at once and utterly dissipated. Who shall say that our sun, which is a star, will not do the same to-morrow, or the next day, and thus the dread prediction of the Scriptures be realized at any moment? Most assuredly we have no guarantee to the contrary, and can only comfort ourselves with the reflection that while hydrogen is certainly there, and also an awful store of force to heat and project, if yet such convulsions are rare in the order of nature, and, therefore, the world may outlast our time. Nevertheless both astronomy and geology inform us that there have been periods of great variation in the heat-giving power of our sun, and we may well be disquieted at the possible approach of a time when "the heavens shall pass away with a great noise, the elements shall melt with fervent heat, and the earth also, and the works that are therein shall be burned up."

EXPERIMENTS ON THE RESISTANCE OF STONES TO CRUSHING.—Mr. C. B. Richards, C. E., has recently experimented upon various kinds of American building stones worked into 1 inch and 1½ inch cubes, with flat end smooth faces. The specimens were crushed between the plane faces of two hardened steel hemispheres, the curved portions of which were seated in corresponding cavities of steel blocks, fixed in the machine. Single thicknesses of lace leather were interposed between the stones and metal surfaces; thus the pressure was uniformly distributed; it was in all cases applied to the faces of the cubes parallel to the natural bed of the stone, and carefully increased to rupture by pouring shot into the hollow weight by which the strain was caused.

Sixteen specimens of granite from six quarries gave from 8,620 to 15,622 pounds, minimum, 9,838 to 13,778 pounds, maximum strength. Fourteen specimens of sandstone from 3 quarries gave 5,806 pounds minimum, and 8,956 to 10,928 pounds, maximum strength. And 10 specimens of white marble from 3 quarries gave from 3,905 to 12,917 minimum, and 5,976 to 13,972 pounds maximum strength. Each was a 1 inch cube. The specimens failed by breaking into slender prisms and pyramids with axes normal to the pressure.

O. W. HOLMES ON "DARWINISM."—O. W. Holmes asks and thus answers the question: What is the secret of the profound interest which "Darwinism" has excited in the minds and hearts of more persons than dare to confess their doubts and hopes? It is because it restores Nature to its place as a true divine manifestation. It is that it removes the traditional curse from that helpless infant lying in its mother's arms. It is that it lifts from the shoulders of man the responsibility for the fact of death. It is that, if it is true, woman can no longer be taunted with having brought down on herself the pangs which make her sex a martyrdom. If development upward is the general law of the race, if we have grown by natural evolution out of the cave-men, and even less human forms of life we have everything to hope for the future. That the question can be discussed without offense, shows that we are entering on a new era, a revival greater than that of letters, the revival of humanity.

A NEW GALVANIC BATTERY.—Gaiiffe's new galvanic battery consists of a vessel in which are contained a plate of lead and a plate of zinc. The lead reaches to the bottom, while the zinc is but half as long. The bottom of the vessel is covered with a layer of red oxide of lead, and the exciting fluid is water containing 10 per cent. of sal ammoniac. The electro-motive power of this battery is estimated at one third that of a Bunsen cell. Its internal resistance is very slight and it is said to be very constant. It has the merit of cheapness.

NEW HYGROSCOPIC TESTS.—A new test paper to indicate the amount of atmospheric moisture has been suggested. It is a kind of a hygroscopic, in which use is made of the property of salts of cobalt, to be bluish when dry, and to become reddish by moisture. Strips of paper are dipped in a solution of cobalt salt, common salt and mucilage, and preserved in a tight bottle. When exposed to the air, a change from blue to pink gives an indication of the amount of moisture.

MOLECULAR PHENOMENA OF IRON.—M. Yore mentions an interesting fact concerning iron when under the influence of heat and strains. A strained iron wire was heated to redness by a current of voltaic electricity, and then, the current being discontinued, was allowed to cool. It was observed that there arrived a moment in the process of cooling at which the wire suddenly elongated, and then gradually shortened, until it became perfectly cold, remaining, however, permanently elongated. No other metal besides iron is known to exhibit this peculiarity—and the phenomenon is supposed to be owing to a momentary molecular change. This change, it is thought, would probably happen in large masses of wrought iron, and would come into operation in various cases where these masses are subjected to the conjoint influence of heat and strains.—*Iron Age*.

BLOOD GLOBULES.—The number of blood globules is greater in mammals than in birds, in the latter than in fishes. The number is almost always in an inverse ratio to the volume of the globules; the relation between number and volume is not proportional. Birds gain more by the augmentation of the volume of their blood globules than they lose by the diminution in their number.

IMMUTABILITY OF SPECIES.—Cats and dogs embalmed in Egypt four thousand years ago are precisely like those of to-day, said the late Sir David Brewster. What have the revolutionists to say to that fact? Four thousand years are nothing, so gradually are organic changes brought about—would probably be the Darwinian answer.

MECHANICAL PROGRESS.

The Band Saw and Band Sawing.

The future of the band saw is hard to predict; judged upon general principles, and by the saws that govern sawing, we are at once led to conclude that it must supplant every other method. The advantages are so many, and so obvious, that nothing but insurmountable mechanical difficulties can prevent its becoming the standard saw for every kind of use. Analyzing the principles of its action, we may be said to have a blade of superior thinness, capable of tension in varying degrees, moving in right lines through the material, at a speed that is almost unlimited, and can exceed that of circular saws; operating too by machinery consisting only of rotating parts, and of the most simple construction, the sawdust all carried down through the timber offering no obstruction in following lines.

Add to this the peculiar adaption of the band saw to curved lines, and its advantages cannot be overestimated. The speed of sawing, or the cost of sawing, which is much the same thing as the movement of the teeth, is with the band saw almost unlimited. Its performance, contrasted with reciprocating saws for cutting plain sweeps or scroll work, shows a gain of time, or cost, of three or four to one, with the important advantage of being easier to operate, and we may also term it a popular machine with workmen.

Mechanical Difficulties in the Way of its Introduction.

Considering these many important advantages, it would be strange and unusual if they were to be attained without combating mechanical difficulties, that must necessarily exist for a time in every new discovery. The flexion of the steel in passing over the pulleys tends to crystallize and break the saw, unless there is that degree of temper and texture which is known to withstand this bending. This has been the crowing obstacle to the introduction of band saws. It is true that saw manufacture, or steel manufacture, had not until recent years been sufficiently understood to produce perfect blades at low prices. Yet if it had not been for the fear of breaking blades, the band-saw machine, invented seventy years ago, would long since have taken its place as a standard machine for wood cutting. Joining the blades too was regarded as a most difficult operation. Holzappel in his celebrated work on mechanical manipulation, after noticing the band-saw machine of Newberry, already described, speaks of it as a curious machine, and alludes to the supposed difficulty of joining the ribbons, or saws, as an obstacle to its use. That the opinion was based upon experiments we can hardly conclude, for soldering and brazing iron and steel were certainly practised at that date, and well understood.

This matter of joining blades, which will be further noticed, has disappeared as a difficulty, and become so simple a thing as to be performed in a few minutes by those that have no other knowledge of metal working. The breaking of the saw blades by flexion, the first and greatest objection to band sawing, is fast giving way before the improvements in steel and saw manufacture, and before improvements so less important in the machinery for operating the saws.

Joining the blades is no longer a difficulty, but a most simple operation. However there still remains another condition to be overcome that threatens to be more serious, that of resisting the back thrust in band saws. This

matter would at first seem to be one of no great importance, or at least one that would not suggest itself except in actual experiment, and hence it has not had much notice, for up to the present time the use of hand saws has been almost wholly confined to scroll cutting and other kinds of work, when hand feed only has been employed, and the back thrust so inconsiderable as to cause no trouble.

When positive power feed is applied, however, a new set of conditions arise, and the question is, how to resist the abrasion and heat, with a very limited amount of surface, moving at a high velocity, and incapable of being lubricated.

Having stated the general principles that seem to lie at the bottom of band sawing, we now come to the mechanism of machines, and the operation of the saws. Being comparatively a new thing, there is not the usual data on which to base either plans of construction or rules for operating; yet if the development of this business were waited for, there would be but little need of a treatise of any kind to give such information.—*Richard's Treatise on Wood-Working Machines*.

[To be continued.]

A New Railway Brake.

The *Chicago Railway Review* contains the following description of a new atmospheric railway brake, invented by T. E. Sickles, chief engineer and superintendent of the Union Pacific Railroad, and designed to remedy the objections to the Westinghouse contrivance, and especially the use of the air pressure to apply the brake.

Mr. Sickles, in his apparatus, uses a spring to apply the brake, and the air pressure to take it off. The normal condition of the train is with all the brakes applied by action of the springs. If the engineer wishes to start the train he lets on the air pressure, which detaches the spring and leaves the wheels free to move; the pressure is kept upon the pipes, and so long as this done the brakes are kept released.

To apply the brakes, a portion of the whole of the condensed air in the pipe is let off, and the action of the springs applies the brake.

If there be any defect in the connecting pipe, the result can not be serious, the only effect being that the result can not be started, and the engineer must stop and repair the pipe, and re-establish the air pressure before the wheels can run. In the Westinghouse apparatus the engineer has to find out defects by trying to stop, instead of start the train, and the knowledge may be obtained at fatal cost. Suppose, with Sickles' apparatus, that the train breaks in two, the break lets the air out of the pipes, the springs apply themselves to each car, and the entire train is brought to rest.

The entire train is under the instant control of either the conductor or the engineer. By having a cock in each car leading to the air pipe, the conductor—an accident having occurred to any portion of the train—can apply the brake from any car to the entire train; and this he can do as gradually or suddenly as he pleases, by regulating the discharge of air from the pipe. The brake is automatic in case of a brake in the train; the conductor (or a brakeman or passenger, for that matter) can apply it, and the train can not be run unless the apparatus is in order.

ANCIENT TIMBER.—Probably the oldest timber in the world, which has been subjected to the use of man, is that which is found in the ancient temples of Egypt. It is found in connection with stone-work, which is known to be at least 4,000 years old. This wood, and the only wood used in the construction of the temple, is in the form of ties, holding the end of one stone to another in its upper surface. When two blocks were laid in place, then it appears that an excavation about an inch deep was made in each block, into which an hour-glass shaped tie was driven. It is therefore very difficult to force any stone from its position. The ties appear to have been the tamarisk, or chittim wood, of which the ark was constructed, a sacred tree in ancient Egypt, and now very rarely found in the valley of the Nile. Those dovetailed ties are just as sound now as on the day of their insertion. Although fuel is extremely scarce in that country, those bits of wood are not large enough to make it an object with Arabs to leave off layer after layer of heavy stone for so small a prize. Had they been of bronze, half the old temples would have been destroyed ages ago, so precious would they have been for various purposes.

THE NEW MODE OF PILE DRIVING.—James Cass, who is building a wharf at Caytics, on Monterey Bay, being unable to procure a pile-driver, resorted to the novel method of screwing the piles into the ground. He cut a thread, screw-fashion, at the end of each pile, and then after sinking the stick or pile a short distance into the loose soil or sand, worked it windlass-fashion until it had reached a sufficient depth to be firm and secure.

A PECULIAR LOCOMOTIVE.—A new locomotive named the *Anthraxite*, which has been placed on the Albany and Susquehanna Railroad, has six driving wheels and carries its water above the boiler. A tender is thus dispensed with. The firing apparatus is stated to be so arranged that the fires last all day without replenishing, and the furnaces only require damping once a week.

[S. F. Stock and Exchange Board.]

THURSDAY EVENING, March 6

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned:

California.

ALPINE COUNTY.

TARSHISH.—*Alpine Miner*, March 1: Among the returns from assay made last week was this:—Gold \$5 185 72; Silver \$563 39.—Total

I. X. L.—Rumor has it that the I. X. L. Co. have a fine pay ledge in the bottom of the Buckeye No. 1 shaft. This Co. and the Exchange, both running steam hoisting work,

ner are both running steam hoisting works, and expect to be able to supply the mill on Silver Creek with pay ore as early as it can be hauled down from the mine.

AMADOR COUNTY.

HINCKLEY.—Amador Ledger, March 1: After sinking some 40 ft. in the new shaft on this mine they were compelled to give it up on ac-

count of the heavy flow of water. They are now taking out some fine rock from one of the old shafts, though they are not so deep upon the ledge.

KENNELLY.—This mine is holding its own. The Co. are rapidly sinking on the new shaft. The new hoisting works and machinery are working finely, and it is expected that the work-

men will strike the main lead at about 400 feet.

BACON.—We are informed that the proprietors of this mine will erect steam hoisting works and start up about the last of the present month.

GALAVRAS COUNTY.

GWIN.—Calaveras *Chronicle*, March 1: Sinking the south shaft another 100 ft. in depth will commence shortly. The yield of this mine con-

commence shortly. The yield of this mine continues to be great, and there is no interruption of operations. When the next sinking is completed the mine will be opened to the depth of 700 feet.

THE following is mostly condensed from journals published in the interior in proximity to the mines mentioned:

FROM THE PHOTOVOLTAIC, $P = 0.001$ TO 0.002 WATT PER SQUARE CM.

ALPINE COUNTY:

GARLAND MILL.—We learn that this mill at Mosquito Gulch will shortly commence crushing rock from Albright & Rechenbach's mine. Those gentlemen have about 45 tones of ore on their dump that prospects largely and is expected to reward the owners of the mine well for their labor.

MOKELUMNE WATER Co.—This Co's ditch is now thoroughly repaired and any danger from future slides guarded against. There is water in abundance, and all the mining companies

are busily at work, paying no regard to the inclement weather. The great fall of snow in the mountains—protected as it is and has been by

unusually cold weather—is sufficient assurance

that there will be no lack of water during the approaching dry season.

RAILROAD FLAT DISTRICT.—Petticoat stopped work in 450 ft. north level. South level is nearly 500 ft. and extending.... A huge hoiler is being put in position at the Sanderson.

Mosquero District.—The superintendent of the Good Hope is raising in the tunnel for the

purpose of sinking a main shaft below the level of the tunnel. The low grade ore, crushed recently, added to the confidence in the mine. Snow having disappeared a number of other

WEST POINT DISTRICT.—Ohio Consolidated, sinking.... The Zacatero will start up soon, and in good shape.... J. Griggs & Co. have been compelled to quit work in their drain tunnel at

compelled to quit work in their drain tunnel at times. In the mean time they have extracted very fair ore from the surface works.... Woodhouse has some 400 tons of ore on dump. The owners will erect a 10 stamp mill on the mine

STICKLE.—The 20 etampe of this mill are kept going night and day. A few days since

CALAVERAS GOLD MINING Co.—Calaveras Citizen, March 1: This is a Co. organized for the purpose of working three quartz leads located on Indian Creek, about five miles from Murphy's, in this county. The Co. has erected a first class 20 stamp mill with self feeders, amalgamators, Paul processer, etc.—the whole being run by a 90 horse power engine.

dred tons of ore on the dump of a quality superior to any yet crushed. There are 4 shafts on the Co's property, the deepest being down 250 ft., with a well defined lead in the bottom, averaging from \$40 to \$250 per ton. The rock has paid an average of \$20 per ton. The rock

SANDERSON.—They have purchased the engine and boiler at the Hepburn Mill, and are put-

ting them in position on the mine. The 100 ft. level has developed an extensive deposit of high-grade ore.

WOLVERINE.—This mine is also looking extremely well. The last "sink" of 120 ft. has demonstrated the value of quartz ledges in this District, and completely refutes the idea that the pay ore is all near the surface.

PETTCOAT.—This mine has no new developments of importance. The Co. continue to burn large quantities of wood and blast powder in extending the 450 ft. level south from the shaft, with no ore in the face. In fact, this level, 300 ft. in length, has not produced a pound of quartz. If the present workings of this mine had been sunk 600 ft. north from where it is, it would long ago have been producing dividends.

ITEMS.—We learn that times are lovely in the lower end of the county. At Jenny Liad, Craig & Company, are running on good dirt. At Whisky Hill the Bunker Hill Company are running their large hydraulic very successfully. This claim was recently purchased by Mr. George F. Sharp, of San Francisco. A run has already been made this season, which paid over \$100 per day. The Whisky Hill tunnel claim will commence washing again in a few days. A company of practical miners are putting large hydraulic machinery on North Hill, and expect to be running within ten days. This will develop a very extensive body of rich gravel. The Salt Spring Valley Reservoir, belonging to the Quail Hill Mining Water Co. is filled with water, which guarantees a full supply of water until next winter.

EL DORADO.

POAHONTAS.—Cor. *Mountain Democrat*, March 1: I was down in the mine to the 500-ft. level, where the seam of quartz is literally packed with gold. I was astonished with the dazzling sight. The chamber is about 100 ft. in length from the bottom of the shaft; and penetrates the rich seam about 30 ft., the ledge is about 3 ft. thick, of unknown depth, with thousands of tons of rock overhead, which it is fair to suppose is as rich as that which is now in sight.

A HOME DEVELOPMENT.—On Wednesday last Messrs. Shepard and Whitton struck a rich body of pay ore in a shaft they lately commenced sinking on their ledge at a point just back of the Episcopal Church, hardly more than 100 yards from this office. The ledge is clearly developed, with well defined hanging and foot-walls of slate presenting a glassy smoothness of appearance. The body of quartz between the walls is fully 5 ft. in thickness, and from Spring Ravine to the shaft in question they have traced and prospected it with highly satisfactory and very uniform results. In the new shaft they have sunk only 10 ft. The quartz taken out last Wednesday is of an extremely friable and porous character, showing a liberal sprinkling of free gold throughout its surface, and ponding out on rough test at the rate of about 10 cents per pound or \$200 per ton.

MARIPOSA COUNTY.

MARIPOSA ESTATE.—*Mariposa Gazette*, Feb. 28: An increase in the working force on the Bear Valley Mines was made last week and it is reported that the Pine Tree and Josephine Veins are to be worked and that the prospect of good paying ore in both is redoubled to a certainty. It is in contemplation to reopen the Princeton Mine this spring, and to construct a railroad from that point to the Benton Mills. The new vein, discovered by Mr. Easton, is said to be yielding rich ore.

WASHINGTON.—Work is still in progress on the vein and the rock now being taken out looks well. The mill has been temporarily stopped and is being overhauled and repaired.

Cor. from Indian Creek, Feb. 8: Work at mining is going on as usual. Hambridge & Gonnigall, in the Quail Lead, have struck splendid rock in the "shnte," where they are cutting upward for an air shaft.

On Gentry's Gulch, Mr. Coward is still busy getting his mill ready. Mr. Shiner, on Bean's Creek, is nearly down with his new shaft, which shows good rock on each side.

NEVADA COUNTY.

IDAHO.—*Grass Valley Union*, March 4: This mine's monthly run closed on Saturday, the 22d of February. The mill (35 stamps) worked 22 days, and gave gold to the value of \$75,000. For the 6 days ending last Saturday the Idaho cleaned up about \$20,000, which is to be aggregated with the proceeds of the current month. The January run of the Idaho gave about \$72,000.

EUREKA.—This mine with 10 stamps has given about \$47,000 for a month's run. We regret to state that no changes for the better have taken place in the lower depths.

SLATE.—This ledge has done but little crushing during the month, because the roads were so soft that it did not pay to haul the ore from the mine to the mill. Hauling commenced yesterday and the mill was immediately started up. There are about 100 tons of good ore on the dump at the mine. The ledge is large and shows rich mineral.

COE.—This mine has just finished repairing and retimbering the main shaft. A contract to sink the main shaft 50 ft. lower, with the privilege to the contractors to sink 100 ft., was let yesterday.

DAISY HILL.—The mine still continues to send out good milling ore, and has a good sized dump ready for crushing. The last crushing gave \$42 to the load, and the rock now on the dump will, it is estimated, come up to those figures in yield.

GREENHORN.—The mill and mine are working away night and day. The ledge is large, with

beautiful walls, giving every assurance of permanency. The crushing now going on will give something like \$25 to the ton of ore.

GREEN MOUNTAIN.—This mine, during its last business month, made a run of 18 days with its 5 stamp mill, cleaning up gold to the amount of \$2,545. The value of the sulphurets saved is not counted.

HOWARD HILL.—This mine shows a most gratifying improvement. The shaft is down 390 ft. and from the bottom drifts have been run east and west. Both drifts are in good paying ore, with a ledge from 2 to 2½ ft. thick. The quartz of the ledge will pay, according to the judgment of experienced men, at least \$20 a ton. The present workings of the Howard Hill are 100 ft. lower down than any former workings of the mine.

GRASS VALLEY NEW MINING Co.—At present they are prospecting on a ledge formerly known as the Imperial, about one mile from Grass Valley on the Nevada road, on which they are now sinking a fine timbered shaft, 9x1½ ft. in the clear and have a good ledge from 20 inches to 2 ft. thick which prospects well.

PROSPECT M. Co.—They are at present prospecting on the West Idaho ledge on Slate Creek, on which they own 3,000 ft. This ledge was worked some 2 years ago by a company which sunk several shafts, probing the ledge for some 2,000 ft. to water level, with flattering results. From where they are now drifting by the time they reach the center of the hill with their tunnel of 500 ft. with the opportunity of going 150 lower should they wish it at some future time. The ledge has a fine appearance showing free sulphurets, galena and free gold.

KENTUCKY.—This ledge has had considerable money taken out of it in former years, the last 149 loads of rock averaging \$17 per load, and some paying as high as \$30. There has been considerable excitement on this claim lately, in consequence of striking good ore 400 ft. from the main shaft, while doing a few days' work to hold the ground.

INDEPENDENCE CON.—This Co. is still running a tunnel through Independence Hill, near Deadman's Flat. The tunnel is now in the distance of 375 ft., and the rock is very hard. During the last month a foot a day was averaged in running the tunnel. The ledge has not yet been cut, though stringers that bear gold are in the tunnel. The stringers prospect well.

NORTH STAR.—The mine continues to have splendid ore in the new shaft.

GRAVEL MINES.—The hope is on the assessment roll just at this time. Work is being done all the time at the lower depths of Alta Hill.

The Dartmouth is sinking a shaft on the north end of Grass Valley slide, which is the east end of Alta Hill. The gravel from the shaft is being put through a five-stamp battery and the yield is paying expenses.

The Town Talk is doing a little better than it has done heretofore. The mine has paid a clear profit, for two years past, of \$1,200 a month.

The Independent Gravel Co. has a good lead, which adjoins the Town Talk. The gravel and cement are put through the crushing process which saves almost all the gold. This gravel lead appears to run through the Howard Hill claims. In other words, the Howard Hill has good quartz and splendid gravel.

The Picayune Gravel Co., near Rough and Ready, continues to pay largely over the cost of development.

PLACER COUNTY.

ST. PATRICK CO.—*Placer Argus*, March 1: This Co. are prosecuting the work of development on the Crater Mine. The present engine-shaft is being sunk from the 150 ft. to the 230 ft. level. A cross-cut is being driven northerly for the purpose of intersecting the main ledge, which has thus far proved to be the richest of three ledges belonging to the Crater Mine. The rock taken out has paid on an average over \$100 per ton. The ledge being worked evidently connects with what is called the Middle ledge at no very great depth. A new and commodious working shaft is being sunk on the middle ledge, which is intended to be the main working shaft of the mine when completed. The cross-cut which is now being driven northerly from the 160-ft. level, on the engine shaft, is in 20 ft., and will reach the middle ledge in about 10 ft. more. The last rock worked from this mine, and which has just been cleaned up, yielded \$40 per ton.

BELLEVUE.—This mine under the management of Fred Jones has been yielding daily, for the past month, very rich ore from the several shafts. The hand mortar has pounded out over \$2,500, to say nothing of the stores of rich ore in sight in the backs as the shafts are being sunk, and no stopping has been done.

ECLIPSE Co.—They have completed their mill, which has 5 stamps and is run by a burly curdy wheel. The ledge belonging to this Company is 30 inches in width and the rock shows gold, whenever broken, all through it.

GREENE.—The mine continues to richly remunerate the owners. The present shaft is being sunk and is developing a large body of very rich ore.

JULIAN.—This mine is turning out bullion at the rate of \$12 per ton of rock crushed. The mill, which is one of the best in the State, with 20 stamps, crushes 30 tons every 24 hours. The ledge is from 2 to 5 feet in thickness and easily extracted and broken.

COON.—This mine is furnishing rock that pays \$80 per ton at a depth of 20 ft., and increases in richness as the shaft is being sunk.

PLUMAS COUNTY.

TALO.—*Plumas National*, March 1: This Co. of Argentine, have for some time past been put-

ting their mill in order, and started up some 3 week's since. We were shown a day or two ago, something over \$600, the result of 12 day's run of their nine-stamp mill.

ELBOW TUNNEL.—From Mr. Denison we learn that the Elbow Co. are running a large quantity of gravel through their flume, and everything works "to a charm."

GREEN MOUNTAIN.—Some very rich rock is now being taken from this ledge, near Cherokee, and it is thought that the strike will develop a large body of high grade ore.

NEW YORK CO.—Cor. from La Porte: This Co. have struck the highest kind of pay dirt upon some high rock, prospecting from \$1 upwards to the pan—or, as some of the workmen express it, the dirt is lousy with gold.

FOWLER'S DIORITES.—Thomas has the best kind of a prospect, with a tunnel 1,800 ft. in the hill, and owning the largest portion of the claims. He let a contract a few days ago of 100 ft. in solid tunnel for \$14 per foot.

BONDWELL TUNNEL.—This tunnel is still being pushed ahead, being in over 1,100 ft. They are not making so good headway at present, owing to a large quartz ledge running in the tunnel almost parallel with it.

TRINITY COUNTY.

AT WORK.—*Trinity Journal*, March 1: miners throughout the county are at work with a fair supply of water. The storms during the past week have put considerable snow on the mountains and the Spring will probably be an extra one for mining.

Nevada.

ELY DISTRICT.

ALPS.—*Pioche Record*, Feb. 23: The American Flag mill commenced crushing Alps ore last Wednesday. Average pulp assay \$132. The dump is full of rich ore which is being forwarded to the mill daily. The vein is now fully 18 inches in width.

IN PROGRESS. New east and west drifts have been started from the 500-ft. level, and the prospects are good in both directions. The mine was never in better condition than now.

ALADDIN.—Two days since a fine body of quartz was encountered, interspersed with first-class ore. Work is being pushed day and night. Over \$5,000 has already been spent in development.

CHIEF EAST EXTENSION.—Shaft below the 90-ft. level down 110 ft. There is some fine ore on the foot-wall.

MARION.—The shaft is down 285 ft. The ledge is much harder and has some good ore mixed through it, which assays very well.

MONTANA.—The indications have improved wonderfully in the drift for this ledge during the week, and it is almost certain that it will soon be reached.

MAZEPPA.—Work continuing with full forces, and ore breasts all that could be desired, and there is a marked improvement as the development proceeds.

NEWARK.—The main shaft is now down to a depth of 630 ft. and work is being prosecuted with all energy in the shaft and in the south drift.

PHILADELPHIA.—The ore breasts are unchanged. An immense amount of ore is on the dump, and great inconvenience will result if the condition of the roads does not soon improve. Pioche will send out enormous quantities of bullion when sufficient milling facilities are again available.

JOHN PIERCE.—The new shaft is down 325 ft. The rock is harder and has been very hard, but is now coming in softer. A large ledge was cut through the past week, which shows well. It has been located for the company.

PARIAN.—Work has been prosecuted in the Parian with renewed energy. The shaft is now down 84 ft. and a drift has been started north to cut the ledge, left in the foot-wall at the depth of 100 ft.

THE BAY EX.—This mine continues to send up to the surface large amounts of high grade ore daily. Some idea may be formed of the yield of the Raymond & Ely when we state that the local tax on its million product for the last quarter amounts to over \$18,000.

SILVER PEAK.—The rock, during the past week, has been harder than usual, but everything considered, fair progress has been made and is being made. The incline is now down fully 200 ft. Good progress has been made during the week in the tunnel, and the indications are that it has nearly reached the ledge.

STAR OF THE UNION.—We were shown specimens of ore from this promising new ledge, and must say that better looking ore, considering the extent of the vein, we have seldom inspected. The incline is now down nearly 200 ft. and work is pushed ahead with full forces.

ESMERALDA.

Cor. Calistoga Tribune, Feb. 10: There are two quartz mills running, and another one is in course of erection. The mines are principally of silver ore, though there is some gold found in some of them. Among the richest and best developed may be mentioned the Major Thompson and Belle Waddle, the ores from which assays from \$300 to \$1,000 per ton. Besides these there are a great many more that are producing first class ore, and all of them are being developed.

Besides the silver mines there are very extensive borax and salt marshes, which contain millions of dollars worth of these two articles. The borax forms on top of the ground, and is so easily gathered that one man alone, with a shovel, can collect from 3 to 5 tons a day. At present there are only two companies engaged in its manufacture. The Pacific Borax Company own 98 quarter sections of borax land, and are shipping a great deal of borax to San Francisco. Hearse & Co. are making about 4 tons per week of refined borax, which is worth, in San Francisco, 28 cents per pound or \$560 per ton.

REESE RIVER.

OREGON SHAFT.—*Reese River Review*, Feb. 22: This is the deepest shaft in the district and larger quantities of ore are hoisted than from any other works. Seventy-six men are employed here; prospects even better than usual.

BOLTER-HIDE INCLINE.—The cross-cut from the bottom of the incline has been extended 120 ft. at which point a vein of fine ore has been cut.

SOUTH AMERICAN SHAFT.—A cross cut from the 400 ft. level has just cut a vein 12 inches in thickness, but sufficient work has not yet been done in it to develop the vein.

NORTH STAR SHAFT.—There are 16 men at work who have a fine body of ore in the 220-ft. level; we saw a specimen weighing about 50 lbs., which comes from a ledge 18 inches thick; it will mill \$1,500 per ton.

OGDEN INCLINE.—Working a force of 18 men with good ore in the west level.

MOHAWE.—This mine was formerly known as the Saratoga. The prospects in this mine are better than ever. They have just developed an extensive chimney of high grade ore in the west level.

GROVE TUNNEL.—Working 14 men, with good ore throughout the mine.

MORGAN & MUNCEY.—Six men are working here on a fair grade of ore.

JANE.—Four men at work who are at present sinking an incline.

HATFIELD TUNNEL.—There is the same activity displayed here as before, and 12 men are at work, taking out good ore from various parts of the mine.

AUSTIN.—This mine was formerly called the Reese.

Two men are working in the incline at a depth of 125 ft. and taking out some good ore.

S. C. BAKER.—The lessee are taking out very good ore. **PACIFIC MINING Co. (LIMITED).**—There are not over 20 men at work either above or below ground. Sixty tons of ore have been worked the present month in the Manhattan mill, which netted \$8,000 after paying milling charges. There are from 30 to 40 tons of ore in the ore house at present which is supposed to average over \$200 per ton.

SARATOGA.—A pump is being placed in this mine at present; will start up again next week.

BELMONT.

EL DORADO SOUTH CONS. Co.—This Co.'s new mill has already started to its full capacity. The large body of ore in the south works of the El Dorado mine is increasing both in extent and the richness of the ore and lies between two splendid walls; the foot wall is granite and the hanging wall slate. Working this whole mass as it is taken down, it averages \$120 per ton at the mill, but assays as high as \$1,828 have been taken from the screenings of portions of the mass of chlorides.

MONITOR Co.—Still running their fine mill on the high grade Monitor mine, making the lower level northerly through good milling ore. The upper steps look splendid; still drifting back into the hill for a back ledge. Working 70 men. This Co. shipped to-day \$5,100 in bullion, being two days' run.

BELMONT Co.—Still pushing the lower drift, which are continuing to expose good bodies of ore. Taking out good ore from steep above water line.

WASHOE.

ARIZONA & UTAH.—*Gold Hill News*, March 1st: This company is putting up a new boiler house so as to be ready to place in position the new boiler and pump, which are en route.

ARK.—The new building over the shaft is completed. Sinking the shaft is making excellent progress. The tunnel is still driven energetically ahead, the rock in the face working well and good headway being made.

BELCHER.—Daily yield 400 tons. The mine is looking splendidly at all points, and the ore breasts at the 1,000, and 1,100-ft. levels bid fair to hold out for years to come, to say nothing of the immense body now just being opened out at the 1,300 and 1,400 ft. levels. The last mentioned level is but just opened into from the Crown Point, and the ore which is taken out through the Yellow Jacket shaft is of very fine character and high grade. The drift southwest of the 1,200-ft. level to connect with the drift north from the main incline, being pushed ahead as fast as possible.

BALTIMORE CON.—Drift west of the 250 ft. level, now in 342 ft., face in clay and quartz. Shaft down 470 ft. Have commenced cutting out for a new station at that point for a drift to the ledge.

BUCKETE.—Owing to the bad roads the ore hauling has been considerably impeded this week.

BONNY.—The east cross-cut from the 100-ft. level at a depth of 75 ft. from the shaft cut during the week, a body of good ore 10 ft. in width.

CALEDONIA.—The main south drift on the 400-ft. level of the new shaft is continued, cutting during the week some excellent indications of ore.

CHOLLAR-PORTER.—Daily yield 60 tons of ore, the assay value of which is \$32 per ton. The ore breasts are not looking and yielding up to the usual average, although the large tonnage of the daily yield is not attributable to that cause alone. The ore dumps are all full, and it being impossible to get the ore shipped to the mills, it was found necessary to stop the work of a number of men in the mine until the dumps can be cleared.

CHOWN POINT.—The 1,300-ft. level shows improvement in both quantity and quality of the ore being produced, character than in the levels above, and showing an increase of gold, making the bullion worth more than that from the other parts of the mine. It is richest at the south end, next to the Belcher. The drift south at the 1,400-ft. level from the incline, is being driven ahead toward the ore body, and the incline is being sunk at satisfactory rate, considering the hard nature of the rock.

CHOWN POINT RAVINE.—The shaft is cleaned out and repaired to a depth of 200 ft.

EMPIRE.—The main south drift is being energetically driven ahead to connect with the 1,300-ft. level of the Yellow Jacket mine, as soon as possible.

GOULD & CURRY.—Sinking the incline is making good progress, though the rock in the bottom is becoming tough and hard. The main south drift on the 1,600-ft. level to connect with the north drift from the Savage, and the main east drift on the 1,500-ft. level are being driven ahead.

GLOBE.—The raise from the main tunnel is up 35 ft., the whole distance showing good ore.

HALE & MORGAN.—Daily yield, 190 tons of ore from the ore breasts between the 1,300 and 1,400, and 1,400 and 1,500 ft. levels. These ore bodies continue to show a decided improvement in both the looks and the quality of the ore extracted. The main south drift on the 800-ft. level or second station, toward the Chollar, has developed a fine, extensive, and important body of good ore, some 85 ft. east of the old workings of the vein for former years.

IMPERIAL.—The new machinery is being placed in position for operation as fast as it arrives.

JURIST.—Both north and south drift at the 400-ft. level are being driven ahead as usual. The face of the south drift is in very promising-looking quartz and porphyry.

JULIA.—The east drift, 800-ft. level, and west drift, 1,000-ft. level, have made good progress during the past week.

LEE.—The incline is down 90 ft., and has cut into a very large body of high-grade ore, showing gypsum, decomposed quartz and red sulphurets. Assays from this mine have run as high as \$1,800.

NEVADA.—This is one of the old locations on American Flat, and is situated immediately south of the Baldy Mountain Co. and Arizona and Utah. Work was resumed upon it in November last, drifting south from the old adit tunnel, which is 125 ft. in length, along the ledge toward a chimney of ore which crops out quite prominently. The ledge is 22 ft. wide, with a pay streak of ore from 2 to 6 ft. wide, in which the drift is progressing. The drift is now in 110 ft., and below 4 car loads of ore per day is taken out, which is piled up on a dump for milling. It is both silver and gold ore, about half and half of each, silver predominating perhaps a little.

SAVAGE.—Daily yield 100 tons of ore, the assay value of which is \$27 per ton. The main drift south on the 1,600 ft. level made the connection with the south wing of the ledge above on Tuesday last, giving a much needed circulation of pure air. Three cross cuts east to cut the ledge and prospect the level, were immediately commenced at different points along the line of the drift.

STERNA NEVADA.—It has been with extreme difficulty that a sufficient supply of wood could be obtained to keep the mill running during the week.

SUPER HILL.—All the work in the shaft and on the levels is stopped for the present, on account of inability to obtain the necessary supply of wood to keep the pump running and the shaft clear of water.

SCROON.—The rock shows improvement this week, and assays as high as \$90 to the ton.

SETTLE TUNNEL.—Total length, 3,375 ft. The rock works well and good progress is made. Shaft No. 1 is nearly down to the tunnel level.

UNION CON.—The north drift from the main west tunnel is in 150 ft., the face in solid quartz which gives assay of \$12 to \$18 per ton.

VIRGINIA CON.—The main north drift on the 1,157-ft. level from the Gould & Curry shaft is making excellent progress, the entire face of the tunnel in good ore. The body of ore developed by this drift is both extensive and of high grade.

YELLOW JACKET.—Both 1,400 and 1,500-ft. level drifts are progressing as usual; also the cross-cutting at the 1,600-ft. level north.

The First Quartz Mill at Pioche.

Yesterday forenoon, seeing steam rising from the new Floral mill, says the Pioche Record, situate in the northern suburbs of the city, we bent our steps thither, and found fifteen stamps in full operation, with every arrangement made for continuous working. Distant readers will pardon us for considering this event one of transcendent local importance, and giving it more than passing notice, when they are informed that the Floral is the first and only quartz mill at Pioche, all our ores heretofore having been reduced at Bullionville, 10 or 11 miles to the southeast, where wood and water are more abundant.

The Boiler Room.

We first entered the boiler room, and there spent a few moments very profitably. There are two boilers, each fifty inches in interior diameter and 16 feet long. The steam-drum is 30 inches in diameter and nine feet in length. The smoke-stack is 36 inches in diameter and 50 feet high. Live steam pipes and exhaust pipes cross each other at almost every angle, extending from the lower works in all directions. The whole is set in solid stone masonry. From 5 to 6 cords of wood are daily consumed. The boiler room is 30x25 feet in extent, including wood house.

The Engine Room.

Passing from the boilers, we entered the engine room, and there, truly, did we behold, at a glance, so strong a steam mechanism of this highest order to repay us for our half-mile walk through the mud and melting snow. The engines are horizontal with the patent adjustable cut-off attachment, by means of which the power and extent of strokes can be instantaneously regulated while the machinery is in full operation. Wonderful example of the ingenuity and intelligence of man! With its massive steam-chambers, in which is ever confined and ever passing the strength of a hundred stout horses, its gigantic steel arms, tirelessly keeping in perpetual motion hundreds of tons, this mighty motive power operates with the smoothness and regularity of the pocket chronometer. The awkward freight wagon jogging along this road makes more noise. A full detailed description we would feel incompetent to give, had we at our command the space to do so. This fly-wheel is 16 feet in diameter, makes 60 revolutions a minute, and weighs 10,000 pounds. These works, like the boilers, rest on a solid masonry foundation, eight feet deep, which is built up from bed-rock.

Manufacturers.

The steam works of the Floral mill, at Pioche, were turned out by the Risdon Iron and Locomotive Works, corner of Howard and Basal streets, San Francisco; and Pacific Coast artisans need offer no better proof of their ability to cope with manufacturers in other parts of the world than they afford.

Pans and Settlers

There are six combination pans in operation, of highest capacity and constructed from the best models and in the most substantial manner. They are propelled by lighter wheels. And just below them, reached by a short flight of stairs, down a 5-foot breast of masonry, are three settlers, 3 feet in diameter and 3 feet in depth, which are connected in the usual way with the

Retort Room.

Entering the retort room, which is 36x20 feet in extent, we find there every modern facility and appliance for preparing the precious metal ready for coinage. There are three retorts, each of 1,000-pounds capacity with refining works, etc., complete.

The Ore Room

Is supplied with a magnificent drying furnace, 10x31 feet in extent, over which from 20 to 25 tons of ore are easily dried each day, ready for the batteries. But the most important feature of this department, and deserving of special notice, are the excellent dust chambers connected with the batteries and drying furnaces—constructed by Captain Benjamin Evans, the

builder, on an entirely new principle. By means of these the interior of the mill is kept free from flying dust, and almost every particle of the ore is saved. The dust, entering the chambers, ascends a few feet above the roof, where it is arrested and returned below, to be again precipitated into the batteries.

Ore Cars,

Above and below the batteries, nicely adjusted on iron tracks, with turnplate attachments obviate entirely the use of the shovel in removing the ore after pulping.

The Water supply.

A few yards distant is a monster water-tank, which will hold 20,000 gallons, from which water is conveyed through pipes to all parts of the mill. And C. H. Light, the Superintendent of this mill has wisely utilized this inexhaustible supply beyond the regular business wants of the mill, by providing hundreds of feet of hose, extending all through and to the farthest corner of the building, as a precaution against fire. The tank is directly connected, by pipes of sufficient capacity, with the Floral Spring Water Company's works, and, of course, there

The Grizzly Bear (Ursus horribilis).

We introduce our illustration of the grizzly bear; to show, to our readers how marked the contrasts that may pertain to the conditions of a new country, in a very brief period of years. Only twenty years ago, California was known almost entirely as a mining country, with a population of adventurous spirits scattered throughout the length and breadth of the lower Sierras, and oftentimes disputing the right of domain with the native lord of the forests, the Grizzly.

But those early scenes, with all their excitements, dangers and "hairbreadth 'scapes," are now seldom heard of but in the records and history of the past, for now more peaceful pursuits are dominant. Our cut presents us with one of those scenes incident to that in which a trio of miners had for a day turned hunters, and had found game "worthy of their steel," or rather their leaden balls, and whilst one of the

Our Foothill Lands.

Every few weeks we hear of something to strengthen our belief that the foothill lands along the whole length of the Sierra Nevada, adjacent to the placer mining districts of the early days, and the quartz and deep-hill diggings of the present, will eventually become the homes of thousands upon thousands of those who can be content with health, prosperity and moderate gains, in distinction from those who only measure their happiness by the number of broad acres they may possess in the broader valleys or great, lower, arid plains.

We have a letter in hand from Mr. M. F. Gregory, of Jenny Lind, Calaveras county, who speaks favorably of lands in that section, alluviums formed by the Calaveras river, as being finely adapted to the growth of corn, barley, wheat, fruits and vegetables, and gives the yield at 25 cents of wheat and 30 cents of barley per acre. As lands adapted to vineyard culture, the fact has been established, that there are none in the State that can excel those of the foothills, and immigrants would do well to give this vast range of almost unappropriated foothill lands a careful examination before paying double or quadruple prices for the low valley lands, which are no better, for all the purposes of vineyard and general fruit culture.

Just now in the first part of March, go into the markets of San Francisco and on inquiry it will be found that the thousands of boxes of choice, well-kept apples of all the winter varieties known to any country, are almost to a box, Oregon apples; and they are Oregon apples because California does not yet supply her own market with this fruit. Now there are no better lands or climate in Oregon for winter apple production, than are the foothill lands and climates of this State. We speak from a positive knowledge of the fact, and yet there are ten thousand acres of these lands awaiting entry at \$1.25 per acre.

There are localities along the lines of the railroads built or contemplated, through the foothill country, where alter-

nate sections of the finest vineyard, grain and fruit lands are in possession of the railroad incorporators, and from whom an immediate and perfect title can be obtained, at prices ranging from three to ten dollars per acre, depending upon locality, quality of soil and timber; whilst the other sections are still in the hands of the government, subject to entry at established rates.

The Foundation of Our Steam Fleet.

We have shown what we can do in the way of steamship building, in the new steamboat "Eastport," destined for the Coos Bay coal trade. She is of 500 tons and has cost \$150,000. The effects of the trial of this vessel on our coal trade will probably tend in the direction of the reduction of the price of coal in this city. If the "Eastport" is a financial success to her owners, we shall in a couple of years have the entire fleet of sailing coasters replaced by small steamers, and a flourishing ship-building business will as a result spring up in this city. We have on this Coast everything necessary for ship building, and should own all our ships and build them, we, therefore, hail with the building of the "Eastport," as a step, though a small one, in this direction.

Since the beginning of the current harvest year we have dispatched to the United Kingdom a grain fleet of 266 vessels, carrying full cargoes of the finest wheat to the aggregate extent of 400,000 tons.

HUNTERS FIND A GRIZZLY.

is no danger of this supply ever being deficient.

A Blacksmith Shop, As complete as any in this city, is connected with and a part of the mill property.

Aggregate Cost of Mill.

Something over 100,000 feet of lumber was used in the construction of the building, at an average cost of \$75 per 1,000. But as the entire basement is constructed of massive granite walls, the cost of lumber does not bear a great proportion to the entire cost as might be supposed. Elegance, as well as strength and durability, has been considered in the section and completion of the Floral mill, and it is neatly finished and tastefully painted throughout. The aggregate cost is estimated at \$65,000.

Fifteen Stamps Are in Operation, Reducing ore from the Hermes mine; but there is on the ground a vast quantity from the Huhn & Hunt, and other ledges, hauling to the mill continues, and it is probable that no mill in the district will run more regularly than the Floral. Five stamps more, making 20 in all will be put in operation as soon as the necessary material arrives—now on the road from Palisades.

Builder and Management.

Captain Benjamin Evans, assisted by J. C. Clark, was the architect and builder. C. H. Light is General Superintendent; John Collier, amalgamator and general manager, and George W. Coffey, engineer.

We consider the construction of the Floral mill another important guarantee of the permanence and continued growth and prosperity of Pioche.

There is one fact about printers that we have always noticed: They are not over-fond of "pi," but you ought to see how they will "disturb" sweet morsels of mince-pie to their proper "box!"

party finds himself unexpectedly taking an inside view of a Grizzly's face, under circumstances of startling interest, his comrades, at an exceedingly short range, are about to pour in a broadside volley, that if anything saves the half prostrate, hat and gunforsaken miner and hunter, from a bad chawing up, that volley must. And thus we leave him—as is sometimes said—"in the hands of fate," but to our eyes looking more like the paws of a grizzly. The natural history of this grizzly in very few words is this: It inhabits the Rocky Mountains and the mountains to the west of them, to the Pacific ocean. Is of all this bear tribe the most savage and ferocious, and this most to be dreaded for size and strength.

BELCHER AND CROWN POINT.—The improvement in the ore production of the Belcher and Crown Point is apparent in the returns of ore crushed for January and the first two weeks of February, as follows:

	Belcher.			Crown Point.		
	Tons.	Average.	Amount.	Tons.	Average.	Amount.
January...	8,501	\$51.46	\$417,489	15,000	\$41.43	\$621,450
Feb. 14 days..	4,413	50.00	265,580	6,981	50.00	349,050

In the latter part of January the 13th level in the Crown Point was tapped, and since then the ore raised from it gradually increases. The same level in the Belcher has now been entered from the Crown Point and has been carried south 73 feet. A cross-cut into the vein 10 feet shows high grade ore. The average in that level of the Crown Point is over \$150, and the average of the mill product is constantly rising. There are two other mines in which the ore shows in daily increasing strength.

Good Health.

The Dress of Children.

Should our children be dressed in a manner becoming their tender years and their ceaseless activity, or like the dolls and images seen in the senseless puppet-show? As we look at the children in our cities, we are led to believe the latter is the popular manner.

A child is something given to our keeping, for ne to develop in every possible manner to its utmost, not injuring or cramping one of its God-given powers. The first necessities of a child are love, food, and warmth. The two first are more amply supplied than the latter.

How many mothers are there who will dress these tender ones as warmly as they do themselves? A little babe who has never felt a breath of air till perhaps within a few days or weeks past, is considered warmly dressed if fortunate enough to have on a thin flannel shirt with long sleeves, and over this a thin white material for a dress.

The teething babe is often allowed to sit on the floor, which is by several degrees the coldest part of the room, dressed in a manner which would cause us to shiver with cold. Young children require more clothing than adults, yet they seldom get as much. I well remember, and with gratitude, too, the advice of my physician, while tending a sick teething babe. I asked him why my babe was sick so much?

"Because you don't dress it warm enough." I showed him the long-sleeved delicately-textured flannel shirt, the warm skirt, the little merino dress lined throughout, and the home-knit stockings, reaching above the knees. No matter, says the kind old man, "your babe is ailing and teething; he can neither creep nor walk, hence has no warmth from exercise, and, besides, sits on your floor, which is entirely unfit for a strong, well person, because it is so cold." Straightway the flannels were doubled, and under the dress a warm flannel wrapper, and my babe was warm.

Thin white flannel, such as mothers love to use, has not the necessary warmth.

Stockings should be thick, and knit very long, also fastened by elastic to the waists of skirts, so they may not slip down, exposing the bare leg. In winter a single flannel garment about the neck, chest and arms is insufficient.

Mothers of this generation must consider the physical education and training as of first importance, for by our own weakness we know we cannot impart the robust physique we desire our offspring to possess, therefore our lack must be as far as possible, be made up by the careful, judicious training of our children in young and tender years.—*Science of Health.*

DEATH FROM COLD.—Experiments on animals show that they keep themselves alive as long as they are maintained in a state of half congelation, and die whenever their temperature and circulation are so far restored as to permit the blood-globules disorganized by cold, to be diffused throughout the vessels. Death occurs, therefore, whenever these globules are sufficient to produce a considerable disturbance in the system, that is, whenever the frozen part is at all extensive. An animal entirely frozen, and consequently containing in its congealed blood no globule but those unfit for life, is dead, without possibility of resurrection. Thawing it only restores a soft, flaccid, discolored body, with opaque eyes. If freezing only attacks a limb, it becomes gangrenous, and is destroyed. Pauchet deduced from these examinations judicious, practical conclusions. If it is true that, in cases of partial freezing, the death of the individual is due to the disorganized globules re-entering the circulation and corrupting the blood, it is plain that, the more sudden the invasion of these globules is, the more rapidly death will supervene. It follows that, by resisting this invasion, by means of ligatures, or extremely slow thawing, we might succeed in preventing the poisoning. The diseased globules which, pouring in a flood into the heart and lungs, would imperil life by the sudden alteration of the blood, will apparently disturb it merely in an unimportant way, if they are dropped into the blood by slow degrees.

REMEDY FOR HEADACHE.—Put a handful of salt into a quart of water, add one ounce of spirits of hartshorn and half an ounce of camphorated spirit of wine. Put them quickly into a bottle, and cork tightly to prevent the escape of the spirits. Soak a piece of cloth with the mixture, and apply it to the head; wet the cloth afresh as soon as it gets heated.

Croup.

Croup is one of the most dreaded complaints to which children are liable. It is an inflammation of that delicate membrane which, continued from the mouth, lines the whole inner surface of the larynx and windpipe, and finally of the bronchial tubes, or air-passages.

Both from the importance of its situation and the rapidity with which it runs its course, croup is one of the most dreaded and fatal affections in the range of juvenile diseases.

The symptoms begin with restlessness, which in a few hours is followed by wheezing in the throat and hoarseness, most heard during sleep, while a short, dry cough soon after succeeds, attended with a tightness and constriction in the throat, indicated by the child frequently raising its hand to the part as if to remove some obstruction. The difficulty of breathing becomes rapidly more distressing, and the face assumes an aspect of great anxiety; the veins in the neck become swollen and knotted, or varicose, and the voice, every time the child speaks or coughs, has a sharp metallic ring, which soon settles in a steady sound, like the crow or croupy noise made by fowls when caught and held in the hand—that character, in fact, which has given to the disease the popular name which it bears. The cough, at first dry, is after a time attended by a thick, ropy expectoration, which clinging like glue to the fauces, and extremely difficult to remove, causes the child great suffering to expel, the patient appearing half suffocated in its abortive attempts to void the adhering whitish phlegm. With these symptoms come on thirst, heat, and considerable fever; the pulse is quick and vibrating, while the efforts of the child to obtain air causes it to arch the neck back in a manner most distressing to witness, till the anxiety of countenance and difficulty of inspiration increasing, the little patient expires about the third day, strangled from the interruption of air to the lungs.

The paroxysms of this disease usually come on in the evening, and become intensified about midnight, the patient seeming free and better during the day.

All efforts should be bent to induce the re-absorption of the false membrane, loosen it from its hold of the windpipe, and cause it to be expelled. Warm bathing, or sprinkling with warm water may be resorted to, and moderate vomiting produced until the services of a physician can be secured, a matter which should never be neglected, unless one has had much experience in such cases.

HOW WE GO TO SLEEP.—If the phenomena of sleep were not so common, they would be regarded as among the most marvellous of all our experiments. In sound sleep, all voluntary motion is suspended. The muscles relax, beginning with those which move the body, the large muscles of the legs, then the muscles which move the arms, then the muscles which keep the head erect, then those which support the lower jaw, and, last of all, those which keep the trunk in an upright position. Of the senses, that of sight is the first one to surrender. The muscles which draw up the upper eyelids lose their power, and the eyes close, but the retina loses its sensitiveness to the light, even when the lids remain open. The sense of taste disappears next, then the sense of smell, then that of hearing, and, last of all, the sense of touch, which disappears only in the most profound slumber. When a person is to be roused from slumber, touch is the first sense to respond, then hearing, then smell, then taste as the last, the sluggish of all the senses. Sound sleep, and a plenty of it, is indispensable to health. It is the great restorer of the waste which takes place during our waking and our working hours, and is indispensable to long or happy life.

DEATHS FROM THE BITES OF ANIMALS, ETC., IN 1870.—By the Register General's thirty-fifth report, for 1870, just published, we learn that during that year, in England and Wales, hydrophobia was fatal in thirty-two distinctly ascertained cases, and glanders in four. These two are the only diseases known to be caused to man by his two most intimate domestic animals. Two children, however, died from the bite of dogs—not hydrophobic; one from the bite of a cat, and another from a cat sleeping on its face and so producing suffocation. The bite of a rat and of a ferret were fatal in one instance respectively, and one person, an adult, was stung to death by bees. Singularly enough, the victims in the case of all the bites—dog, cat, rat, and ferret,—were male children. Two hundred and fifty males, and twenty-two females, perished by means of "horses and other animals," exclusive of the large number of accidents connected with railways, tramways, mines, etc., and of the 954 males and 182 females returned as killed from "horse conveyances." The total number of violent deaths in the year was 16,593.—*Land and Water.*

A SINGULAR DISEASE.—Cases of a singular and fatal disease have occurred at Logan, Cache county, Utah. The patient is attacked by a pain in the left knee; the leg below the knee, down to the toes, becomes much swollen, hardened and red, the pain then abates, the swelling recommences above the knee, and extends up to the body, when inflammation seizes the bowels and the patient soon dies. Three cases of this disease have occurred, and the medical man, who has had forty years' practice, says he has never known anything like it before.

A SUBSTITUTE FOR VACCINATION.—A theory, which is not altogether a new one, has recently been revived publicly by Dr. D. S. Woodworth, of Fort Wayne, one of the oldest and most eminent physicians of Indiana. In a letter to the *American Practitioner*, he says that for thirty-four years he has held to the plan of pustulation by tartar-emetic as fully as good a preventive of smallpox as perfect vaccination. He adds that the fact is familiar to physicians that there is an almost exact resemblance between tartar-emetic pustules and vaccine, not only at their full development, but during the successive stages. He asks the question, why this artificial pustulation may not be "just as good a preventive as vaccination since the same process has been gone through with, and the same molecular changes?" and suggests that experiments be made in hospitals to prove this theory.

INBROWING NAILS.—A correspondent to the *British Medical Journal*, recommends the following treatment for this annoying and sometimes obstinate trouble: About twenty years ago, I applied a bit of compressed sponge to afford temporary relief, and was delighted to find that it effected a radical cure. I make the sponge as solid as leather, by wetting and then winding string very tightly round it, and drying it thoroughly. Of this I cut a small pyramidal piece, less than a grain of rice. This I insert beneath the nail, and secure it by strips of adhesive plaster, applied longitudinally, to avoid compression. The sponge soon becomes moist and swollen, keeping the nail from the irritated flesh. Any granulations should previously be destroyed with strong nitric acid. I have adopted this plan upon many occasions, and have never found it to fail.

USEFUL INFORMATION.

First Introduction of Coaches.

Coaches came into general use in England earlier than on the continent of Europe. Queen Elizabeth's state carriage was the first vehicle which was designated by that name in the island. In 1583 the Queen rode from the Somerset House to Paul's Cross, to return thanks after the destruction of the Spanish Armada, in a coach presented to her by Henry, Earl of Arundel. It is described as "a chariot throne, drawn by two white horses." The royal fashion found many imitators; and although the coaches of that period must have been clumsy and uncomfortable, they multiplied so rapidly that Dekker, satirizing the follies of his day, complains that "the wife of every citizen must be jolted" now—a very expressive phrase, since the coaches were made without springs, and the roads were of the most primitive kind. But long after the introduction of coaches it was considered effeminate and disgraceful for men to use them.

Queen Elizabeth always preferred to make her journeys on horseback, and even in old age and sickness took reluctantly to horseback. "In Sir Philip Sidney's time," says Aubrey, "so famous for men-at-arms, it was then held to be as great a disgrace for a young gentleman to be seen riding in the street in a coach as it would now for such a one to be seen in the street in a petticoat and waistcoat; so much has the fashions of the time altered." Like most other improvements, coaches were vehemently attacked, on the ground that they promoted effeminate luxury.

Taylor, the water poet, declares "that house-keeping never decayed till coaches came into England; and much later, in 1673, a Mr. John Cresset wrote a pamphlet urging the abolition of the stage coaches between London and the interior. Among other grave reasons for their suppression, he urged that "such stage coaches make gentlemen come to London on every small occasion, which otherwise they would not do but upon urgent necessity; nay, the convenience of the passage makes their wives often come up, who, rather than come such long journeys upon horseback, would stay at home. Then, when they come to town, they must presently be in the mode, get fine clothes, go to plays and treats, and by these means get such a habit of idleness and love of pleasure as to make them uneasy ever after."

CONVERTING PAPER INTO LEATHER.—It is said that an establishment in Pittsburgh, Pa., has a process for treating paper which makes it much harder and tougher than leather, and so elastic as to resist almost any blow without perceptible compression, while it can be worked very easily and cheaply. A French inventor has a similar process, and is now in this country making arrangements for an exhaustive trial of the material for ship armor. It has been approved of by several naval officers who have seen it, and who express an opinion that most valuable service may be rendered by it.

IMPROVEMENT IN CASTOR OIL.—An Italian chemist named Croppi, a resident of Forli, has discovered a process by which castor oil is rendered tasteless and odorless, while its efficacy and emetic quality, which makes this best of cathartics repugnant to so many, is not in the least lessened. Sig. Croppi's invention will prove a great blessing to consumers of castor oil, and its introduction into American medical practice will undoubtedly follow.

Air Guns.

Probably the most perfect air guns in the world are those made in London for the use of British poachers. As they make no smoke, and consequently no smell, they are not so easily detected as firearms when used in game preserves. It is a mistake, however, to suppose that they make no noise. When charged, so as to produce the effects above described, the report is quite sharp—fully as sharp as that produced by gunpowder. When lightly charged, the report is of course diminished; but the force with which the bullet is projected is also proportionately lessened, and so is the recoil. As a weapon for secret assassination, therefore, the air gun does not possess much advantage over a good rifle-barrel.

Few persons are, however, aware of the slight charge of powder or air that is necessary to produce a fatal wound at short distances. Experience teaches us that a bullet that will go through a half-inch board will kill a man if it strikes him in a vital and not too well protected part. Now a bullet can be projected from a rifle with a force sufficient to pierce such a board at twelve paces, by means of a charge of powder not greater than that which will lie on a silver three-cent piece; and provided the charge be ignited quietly, as by a pill luck, the noise of the explosion will not attract the attention of persons who are sixty yards distant. The small pistols in common use make very little noise, except when discharged in confined places; and yet, if the ball should strike a vital part, death may be caused instantaneously by a wound from them. The only advantages possessed by the air gun are its perfect cleanliness and the fact that the parts are not liable to be corroded and rusted. It never requires cleaning; but the labor of charging the condenser may be fairly offset against the labor involved in cleaning ordinary fire-arms after they have been used.—*Industrial Monthly.*

A NEGLECTED SOURCE OF FOOD.—THE AFRICAN EARTH-NUT.—Dr. Muter, in the pages of *The Food Journal*, calls attention to what he terms a neglected source of food. Some time ago while investigating color by means of the microscope, he discovered an ingredient employed by way of adulteration to which he could give no name. Subsequently, he had a sample of a substance offered at the Mark Lane Exchange as an article of food for cattle, forwarded to him for analysis. It now becomes necessary to deal with the matter seriously, and so further microscopic investigation led to the discovery that the mysterious ingredient was simply the flour of the African pea or earth-nut. Dr. Muter declares, however, that the bean of this peanut is an excellent substance, which, instead of being used only as food for cattle, or by some adulterators more enlightened than their neighbors, should be everywhere recognized as a marketable article of human diet.

THE TRUE VITALITY OF LIFE.—The mere lapse of years is not life. To eat and drink and sleep; to be exposed to the darkness and the light; to pace round in the mill of habit and turn thought into an implement of trade—this is not life. In all but a poor fraction of the consciousness of humanity is awakened; and the sanctities will eluminate which will make it worth while to be. Knowledge, truth, love, beauty, goodness, faith, alone can give vitality to the mechanism of existence. The laugh of mirth that vibrates through the heart; the tears that freshen the dry wastes within; the music that brings childhood back; the prayer that calls the future near; the doubt that makes us meditate; the death that startles us with mystery; the hardship that forces us to struggle; the anxiety that ends in trust—are the nourishment of our natural being.

Facts for Business Men.

My success is owing to my liberality in advertising.—Bonner.

Advertising has furnished me with a competence.—Amos Lawrence.

I advertised my productions and made money.—Nicholas Longworth.

Constant and persistent advertising is a sure prelude to wealth.—Stephen Girard.

He who invests one dollar in business should invest one dollar in advertising that business.—A. T. Stewart.

A NOVEL RAT TRAP.—A resident of Newburyport, Mass., whose house is infested with rats, has a novel method of capturing them. On returning at night he sets his traps, which consists of a number of lines, to which are attached tomcod hooks covered with bits of meat. These are suspended a few inches above the floor and connected by a cross line, to which is attached a line running to his bedside, which rings a small bell when a rat is caught. The rats go for the bait, the bell rings and the watcher enters with a club and exterminates them.

ADVICE TO WORKING MEN.—Above all, to be a successful mechanic, you must be a mathematician. Unless you can conquer the mathematics of this trade, you will always have to drudge at the hardest work done. With a thorough practical knowledge of the work and the principles underlying it, you will soon rise above the lathe and file. Study and work together.

Table of Contents.

GENERAL EDITORIALS.—Economy of Fuel—Using Steam Expensively; Stevens' Oxyhydrogen Furnace, \$15. Our Foothill Land, 150. Torpedomania; Academy of Sciences, 152. Steam vs. Sail—Cheap Coal in San Francisco; Wood-Working Machinery; What to Do with Our Boys, 153. Notice to Inventors, 156. **ILLUSTRATIONS.**—A Pulverizing Barrel, 145. Huntere Find a Grizzly, 150. Views of Mare Island Navy Yard, Vallejo, California, 153.

USEFUL INFORMATION.—First Introduction of Coaches; Air Gun; A Neglected Source of Food; The True Vitality of Life; Facts for Business Men, 151.

GOOD HEALTH.—The Dress of Children; Death from Cold; Group; How We Go to Sleep; Deaths from the Bites of Animals, Etc., 151.

SCIENTIFIC PROGRESS.—Do Plants Exhale Carbonic Acid; Are We Witnessing the Formation of New Stars; The Silver Light; Solar Flare—A Fearful Possibility; Experiments on the Resistance of Stones to Crushing; O. W. Holmes on Darwinism; A New Galvanic Battery; New Hydroscopic Tests; Molecular Phenomena of Iron; Blood Globules; Immutability of Species, 147.

MECHANICAL PROGRESS.—The Band Saw and Band Sawing; A New Railway Brake; Ancient Timber; The New Mode of Pile Driving; A Peculiar Locomotive, 147.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 148.

MINING SUMMARY from various counties in California and Nevada, 149.

MISCELLANEOUS.—Resources of Utah—Some of the Principal Mines—Continued; The Metallurgy of Gold and Silver; African Gold Mines; American vs. British Mines; Plumbago Mines; Pacific Ports; Plumbago Mines; Quicksilver in Napa and Vallejo, 146. The first Quartz Mill at Pioche, 150. Mammoth Copper Mine; Bullion Product of the United States; Silver Peak Mining Company; Mount Diablo Coal Mines; Rich Ore; New Atlantic Telegraph Cable, 154. New Incorporations; Meetings and Elections, 156.

A HANDSOME GIFT.—The entire property of the Toland Medical College, including building, grounds, philosophical apparatus, anatomical preparations and models, library, etc., valued at \$75,000, has been presented by the Trustees of the Toland Medical College to the University of California. The institution will accordingly, be hereafter under the control of the Board of Regents of the University. The only condition is that it is to be devoted as heretofore to medical education. The gift is due mainly to the munificence of Dr. H. H. Toland.

SPECIMENS.—We have received some very handsome specimens of argenteiferous galena from the Benton mine Inyo county from Mr. Thos. E. Jones. Some of the ore runs as high as \$1,500 per ton. This class of ore is shipped to Swansea for reduction. Some pieces of rock are heartily stained with copper with peculiarly formed crystals. The ledges are four or five feet wide and a pay streak of 18 inches in thickness.

REDWOOD CASES.—Experiments have been tried with the view of substituting the Redwood for Oak, in the making of wine casks, and it seemed for a time as though it might prove a success; but now there comes up a different view of the subject, for it is said by an experienced wine-grower that the wood will absorb a gallon a week; moreover, the casks at the end of the second year become so wet they are difficult to handle; also they leak badly.

VIENNA EXPOSITION.—It is stated that the United States will be much better represented at the Vienna Exposition than was at first expected. The government vessel which was to have sailed this week has a full cargo.

The net gold product of the San Francisco Assaying and Refining works for February was 48,292 ounces, valued at \$938,780.

Torpedomania.

"As everybody has his favorite stimulant, upon which he falls back when sated with variety, or unwell, so the American has his favorite weapon. It was once a howie-knife, then a rifle, then a Rodman, but at present it is a torpedo. "Give us torpedoes and we are invincible, is the popular cry."—*Broad Arrow*.

The wave of somewhat ridiculous, yet withal universal, panic agitated by the startling result of the Franco-Prussian war has, it seems, produced a slight ripple of excitement even here. Though lessened, naturally, by distance, it has registered itself in the Ordinance gage, and its fluctuations are perceptible in the columns of the press. Now, while we enjoyed heartily England's periodic scare, we cannot afford to disregard our own more rational (because less wild and more sustained) desire for adequate protection. To return to the tidal wave simile: England, where the disturbance first manifested itself, has already settled down to its usual calm and will remain so till the next convulsion, while we are still rocking on the less violent surges.

Personally, we have no especial prejudice against torpedoes, though we might perhaps be forgiven, if the word conjured up disagreeable reminiscences of unfortunate conjunctions of Fourth-of-July, silk-hats, sawdust, small pebbles and small boys. But the amount of interest shown in accounts of newly invented torpedoes, with the confidence they, as a means of national defense, seem to inspire, call for a brief summary of the present status of the much discussed "torpedo question."

Torpedoes are broadly divided into two classes, known as "fixed" and "movable." By the former term we understand those constructed on the *ne tange* me principles of the hedge-hog; by the latter, such as are made with a view to active offensive operations. Fixed torpedoes were successfully used by Russia in the Crimea, and again by the South in our civil war. Their utility, while necessarily limited, is so well appreciated in military circles that they will be always looked upon as an important auxiliary arm. It is well to keep their exact position and value in mind. So much ingenuity has been expended in devising modes of placing and exploding them that they may be considered to have reached the limit of perfectibility.

It is with the movable class, however, that we have especially to deal. Ever since Fulton's first conception of a submarine boat it has been implicitly believed that if a way of moving at will under water, or even partially submerged, could only be discovered, the existing power of navies would be destroyed and a complete revolution in the art of war effected. A great deal of money has been spent, and many lives lost by perilous experiments in this direction. To recall one most touching instance: a submarine torpedo-boat built by the rebels to attack the blockading fleet off Charleston, after having been twice sunk and raised, went to the bottom for the last time in command of a brave lieutenant, who had been the sole survivor of a previous forlorn hope. The newest torpedoes, as the Ericsson, the Lay and the British fish and rocket types, being self-propelling, are directed from a vessel or the shore, thus lessening the danger to their users.

The commission appointed by government to examine the comparative merits of these new "internals" is empowered to expend a large sum in costly experiments; and, in fact, the torpedo item is a most serious one in the ordinance expenses. This commission has distinguished itself, thus far, principally by its warm recommendation of the Lay torpedo, about which we have heard so much and learned so little. It is utterly impossible to give an explanation which shall do it justice in anything short of a War Department report. Its main features are the use of carbonic acid in a condensed state as the motive, and electricity (our mechanical panacea) as the controlling power. It certainly deserves credit as the triumph of intricacy, (as any one who has attempted to follow the published descriptions will sorrowfully testify), and consequent costliness. Suffice it to say that in two trials at Newport it failed in its professed ability to be directed accurately. Nor do we see any marked improvement in any of the other models. At least so the partisans of the respective torpedoes seem to think, for they agree with charming unanimity in denouncing each other's pets. And yet this is only one-half the promise that the advocates of movable torpedoes stand pledged to. If they do not succeed here, of course it

makes little difference how or when their machines explode; provided the latter, with their usual sagacity and discrimination, do not molest us. Nothing less than an unerring aim, high speed, certainty of ignition at this precise spot and time, safety to the manipulators and, above all, simplicity, is required. As yet this point has not been reached. It probably will not till the millennium—and then we won't want such expensive fire-works—as the combination of requisites, each in itself a *sine qua non*, is well-nigh overpowering. Let patentees work out their own experiments and foot their own bills. To be sure it is said that our national economy is becoming parsimony. But why not work to the best advantage? With the present shame of our gallant Navy should we become monomaniacs on the subject of what the *Broad Arrow* (from which our text), an impartial witness, calls "an arm so ticklish to manage, and so untried in real warfare, either on the offensive or the defensive?"

Well, the inventors may console themselves with our heartiest wishes for their success; for when the Gallipagos, defended by a joint committee consisting of a French chemist, a Yankee mechanic and the nameless individual ss Chairmen, defies the allied fleets of the world, we may proclaim the advent of the era of peace.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday evening last; President Davidson in the chair. John H. Carmany and Robert Robinson were elected resident members and W. N. Lockington a corresponding member.

Donations.

Several additions to the library were presented and Dr. Kellogg presented and read descriptions of a number of new plants peculiar to this coast, as follows:

Hedeoma pumila: A new species of pennyroyal, found at Webb's Landing, on the San Joaquin river.

Nema racemosa: Found at Cisco, in the Sierra Nevada, near the railroad, and in the Coast mountains.

Calycadenia plunioja: Sent by an unknown friend from Stockton, without note or comment. The crowning glory of a species of fragrant fall plants, with yellow blossoms.

Calia Californica: From Mendocino county. *Macrorhynchus Harfordii*: Found on R. E. C. Stern's place at Petshuma; a species of fall dandelion.

Etholera quadrivalvis, hirsuta: Woolly-seeded variety of the evening primrose, having purple spotted flowers, and bark yielding a strong fibre.

Mr. Lick's Gift.

President Davidson announced to the Academy that the recent donation of a valuable building site by James Lick had been appropriately acknowledged by the Board of Trustees, and the following minute of proceedings had been presented personally to Mr. Lick, accompanied by a letter from the president:

At a special meeting of the Trustees of the California Academy of Sciences, held at their rooms February 18th, A. D. 1873, to take action upon the deed of property made by James Lick of the county of Santa Clara, the following expression of the sentiments of the Academy was adopted.

The unexpected and unsolicited gift of our fellow member, James Lick, to the California Academy of Sciences, is so far beyond our sanguine expectations that we cannot express to him in adequate words our heartfelt thanks for this maturely considered and magnificent act.

It emulates the richest bequests of Europe and the United States for assisting the pursuit of knowledge, and places every devotee of science throughout the world, and for all time, under the deepest obligations to the donor.

The California Academy of Sciences accepts the deed with its conditions and every member will strive to prove by his unswerving efforts to fulfill them, that the desire of James Lick "to promote the diffusion of science" is deeply appreciated. Having struggled unaided, but hopefully, for twenty years in the cause of science on this coast, the members of the Academy are inspired with renewed faith in their efforts, and believe there is an awakened thirst for scientific research and knowledge, which will prompt our citizens to emulate the noble example of James Lick.

The trustees in a body will wait upon our benefactor to present these sentiments, and to offer the sincere thanks of the Academy for this exhibition of his munificent liberality, with the assurance of the personal efforts of every member to faithfully endeavor to carry out his wishes in the spirit in which they are made.

George Davidson, President; John Hewston, Jr., Vice-President; Charles G. Yale, Secretary, Elisha Brooks, Treasurer; Robert E. C. Stearns, Oliver Eldridge, Thos. P. Madden, David D. Colton.

The President then read an address on the subject of Mr. Lick's gift, saying that the Academy needed \$200,000 to build the structure

and maintain it, and entertains no doubt of the society being able to raise the money.

Alfalfa.

Dr. Gibbons showed a curious specimen of alfalfa, exhibiting its adaptability to different circumstances of growth. It was the remains of a growth of alfalfa on Rincon Hill, at the Second street cut, in this city. The soil had been gradually washed away, leaving the root exposed, but it continued to grow. The extremity of the root was in a claysy soil. The root was more than an inch in diameter. It showed a remarkable tenacity of life in the plant.

Dr. Kellogg said that he had seen places where the alfalfa root was exposed for eight feet by a bank, showing how it obtained its moisture in dry seasons, by the roots being so long. Alfalfa, when sown on the floating islands of the San Joaquin river, instead of running roots down as it does under ordinary circumstances, branches out from three to six inches, making very good feed. It is important to know that, although it suits dry soil admirably, it also adapts itself to wet soil, and in that case does not run down to any depth.

Judge Hastings remarked that the alfalfa, when on lands subject to overflow, say for a week at a time, dies, and has to be sown every year. Upon little exposure to water it is killed.

Sponges.

Dr. Hewston referred to a parasite in an ordinary "abalone" from Pigeon Point, which presented also a specimen of the official sponges. If we really have this sponge on the Coast it will be a great thing for California.

Professor Davidson said the commercial value of the San Diego sponges was about \$10 a pound.

Gravels of Placer County.

Professor Davidson, in referring to a paper read at a previous meeting by Dr. Willey, on the gravels of Placer County (published in the MINING AND SCIENTIFIC PRESS of Feb. 15th) said that the writer thought that it was not this water that caused the gravel. Professor Davidson thought that the overflow of tufaceous lava and the water too were the cause.

Dr. Willey said he meant it was not by water alone, but spoke of the immense deposits and could not see that the ancient river system was so clearly marked out as was supposed. He was at a loss to tell how the cement could be formed by the mere action of rivers. Mr. Hanks had examined the cement and found that it contained the elements of granite. A reason of its formation might be found in glacial action. Another point he noticed was the total disappearance of everything but quartz in that part of the country. The cement may possibly represent the pulverized granites. Many forces had been at work.

Professor Davidson thought that if the cement should prove to be decomposed quartz we could account for it by glacial action, but how can we account for the great abundance of rounded pebbles. Professor Whitney had commenced at the highest point of the American River, where gravel was formed and when accurately measured and put on paper it became evident that the new river was 1,500 feet below the old one when the gravels were formed. The same difference of elevation was apparent in the Yuba River.

Another Gift.

Judge S. C. Hastings, of this city, stated that he was ready to join with any twenty or any ten other gentlemen, and make up the sum of \$200,000 to erect the building on the lot given by Mr. Lick. He expressed his willingness to give \$20,000.

Miscellaneous Proceedings.

A paper, by F. E. Durant, was read, on the nature of liquids contained in mineral substances, their properties being determined by spectrum analysis.

An interesting paper, founded on the observations of John Applegate, an old resident of the San Joaquin Valley, was read, on a curious deposit noted in that locality in the fall of the year, in some respects resembling the manna described in Scripture and by Josephus, and known as honey dew. No conclusion as to its origin has yet been attained. It is collected by the honey-bees and deposited in cells, and a specimen in that form was presented to the Academy.

Mr. Lorquin gave a description of a species of California vulture, recently captured by him. It differs from those described in the Railroad Reports and other works, having down upon its neck, instead of the neck being bare. The specimen measured nine feet ten inches, from tip to tip.

CONGRESSIONAL MATTERS.—By the adjournment of Congress a number of bills of interest to the Pacific Coast failed to be acted upon and died with the session. Among them were the bills to incorporate the Utah Railroad and Mining Company and the Colorado River Railroad Company; to provide for the entry of lands as agricultural unless specifically shown to be mineral; granting the right of way for the Mare Island submarine tunnel; for subsidizing the Australian Steamship Line; for granting lands to the Northern Coast, San Diego and San Bernardino and Wilmington and Wickenburg Railroad Companies; to aid the Pioche and Utah Central Railroad; to encourage telegraph communication with Asia; to aid in the construction of the Sutro Tunnel; and also the Goat Island Bill.

Steam vs. Sail--Cheap Coal in San Francisco.

The new steamer "Eastport," which was launched recently, made her trial trip on the 22d ult. for the purpose of testing her steaming and sailing qualities, and as far as could be judged was very successful. She was built by Captain Olof Read, and engineered by the Risdon Iron and Locomotive Works for Messrs. Lawrence Pool, Donald Beadle, George Fritch and R. D. Chandler, for the purpose of carrying coal from Coos Bay to San Francisco, and is designed to test the advantages of freighting by steam instead of the usual way by sailing vessels. If successful, the owners hope to place coal in the San Francisco market, with equal regularity and condition, and give consumers the same advantages now obtained by those using Mount Diablo coal.

In order to compete successfully with sailing vessels it was necessary to combine large carrying capacity, every convenience to handle the freight, moderate speed, with the smallest consumption of fuel, comfortable but limited passenger accommodations, and yet to be of such dimensions and draught as to enable them to navigate the waters to the coal mines at the head of Coos Bay. Of these various qualifications the rate of speed and consumption of fuel were the only ones tested on the trial trip. The former exceeds the expectations of the owners, and marked by the patent log $9\frac{1}{4}$ miles per hour; the recorded consumption of fuel being ten tons per day, or $3\frac{1}{2}$ pounds of Coos Bay coal per indicated horse power, a result never before attained on those waters.

The dimensions of the "Eastport" are as follows: Length, 160 feet; width of beam, $32\frac{1}{2}$ feet; depth of hold, $11\frac{1}{2}$ feet; 500 tons burden; she is planked with four-inch plank, and constructed in the strongest manner. The engine is direct acting, surface condensing and is exceedingly well made. The engine, made from the most modern of English plans, is remarkably strong and compact; indeed, to one accustomed to the engines used in the San Francisco waters, with the labyrinth of pipes, valves, levers, etc., it is a perfect model of simplicity. The cylinder measures 34 inches in diameter, with a 30-inch stroke. The propeller is 9 feet in diameter, 14 feet pitch and runs with 35 to 40 pounds of steam, following 11-30th of the stroke and averages 395 indicated horse-power, making 74 revolutions per minute. During the trial trip, when it is not usual to have everything in first-rate order, she steamed altogether (stoppages allowed for) 9 hours and indicated an average of 350 horse-power, upon a consumption of 4 tons of Coos Bay Coal.

This result released the builders from that part of their contract which guaranteed a certain number of horse-power upon a specific consumption of fuel, and satisfied the owners that they had the cheapest running boat on the Western waters.

The Risdon Iron and Locomotive Works offered to build a ship and engine here guaranteeing a certain speed, consumption of fuel, draft of water and specified amount of tonnage, thereby fixing the rate of carrying a ton of freight one mile, which is the usual form of contract with the first-class builders, who are thus enabled by combining and designing the hull and engines to give the most satisfactory results. The machinery was designed and erected under the superintendence of George Dickey, who is a practical shipbuilder and engineer, and has for many years had the management of an extensive ship yard and engine works in Scotland, and who is now settled in San Francisco, waiting patiently for that much-hoped-for event "the revival of American shipbuilding," and hopes yet to see California take a foremost rank and see her ships in every port where a dollar can be made.

The "Eastport" has gone on her first trip to Coos Bay and we will lay before our readers a farther account of this new enterprise upon her return. It is to be hoped that it will be entirely successful and that the owners can afford to deliver coal here at a profit to themselves at much cheaper rates than is now done. Nothing that we know of would be of more advantage to our manufacturing interests than cheap fuel.

SAN FRANCISCO MINT.--The coinage at the San Francisco Mint for February was as follows: Double Eagles, \$1,290,000; silver dollars, \$700; half dollars, \$2,500; half dimes, \$16,200; total, \$1,219,000.

Mare Island Navy Yard.

Soon after the influx of gold-seekers had demonstrated the fact that California was to become a populous and important State in the American Union, the Government, with its usual characteristic foresight, began to look round for a site for a Navy Yard. Mare Island, lying between Napa River and San Pablo Bay, a short distance below the Straits of Carquinez, seemed to present the most suitable point for such a location, and Commodore Farragut was instructed in 1854, to take possession of the same. The Island comprises an area of some 600 acres, exclusive of water surface, upon which has been erected immense storerooms, smitheries, foundries, carpenter and machine

MARE ISLAND NAVY YARD, VALLEJO, CAL.

shops, timber sheds, quarters for officers and men, and an extensive naval hospital--the whole constructed of brick, on the most approved plans, and in the most substantial manner. Stone quays, sectional dry-docks, basins, and railways, magazines, etc., have also been built, and all with a view to the utmost attainable efficiency, and on a scale commensurate

every night. Indeed, four times a day, the channel between it and the mainland swarms with little boats carrying the laborers to and fro, and presenting quite an interesting and busy appearance.

On approaching the Island, the large, dry-dock, hospital, officers' dwellings, shops, etc., together with the numerous Government vessels, lying "in ordinary," gracefully in the river, presents a pleasing spectacle. The upper view represents the machine shops and yard, with two monitors lying in the river.

Everything is as neat as abundance of time and labor, with the characteristic nautical cleanliness can make it. The cannon are laid in rows, and the halls piled with mathematical nicety, suggesting that the Government is

fully alive to the truth of that trite expression: "In time of peace prepare for war."

The lower cut shows a few of the vessels lying at the docks. The one in the foreground is the old "Independence," of immense size, like all the old-fashioned line-of-battle ships. The dismantled one is the "Mohican," which is shortly to be rebuilt. The "Resaca" lies in

VESSELS AT THE NAVY YARD.

with the growing and future wants of the Pacific Coast.

Anchorages in the stream is good, and vessels of the largest class can approach quite near the shore. There is a ferry, that runs every hour between the Island and Vallejo, directly opposite which it is located. When strangers land on the Island they are received by a guard, no one being permitted to traverse the Island without a pass.

The origin of the name of the Island is said by some to have arisen from the circumstance that a ship-wrecked mare, belonging to Gen. Vallejo, once reached the Island in safety after much peril. Others claim that it took its name from having formerly been employed as a breeding ground.

From five to eighteen hundred workmen are employed on the Island, all of whom live at Vallejo, as no workmen are allowed to domicile on the Island, which must be entirely cleared

the background. She was recently sold by the Government, and will shortly be placed on Goodall and Nelson's line. The large derrick for taking boilers and heavy machinery out of the vessel is known as, "Bishop's boom derrick." The buildings shown are the workshops of the Bureau of Construction.

A NARROW GAUGE ROAD is being built by a local company from San Luis Obispo to the landing, on the coast, a distance of nine miles. The landing is an open roadstead, or little better, when passengers have to be taken ashore in small boats and hoisted out, and it is quite difficult to load or unload small vessels. If the harbor were improved so that it would be safe, the railroad would be of much more benefit than it is likely to be. But perhaps the residents think if the road is built first, the harbor will be remedied afterward. The country back of San Luis Obispo is used mainly for sheep and cattle ranges, farms being comparatively few and far between.

Wood-Working Machines.

The importance of the wood-working interest gives it a rank among the industries of the country that should entitle it to much more consideration in our technical literature than it has heretofore received. The endless variety of the machinery which is now required to perform the work in wood that was formerly done by hand, has created a want for some such extensive and practical hand-book, as has long been supplied to almost every other branch of the industrial arts; but with the exception of a few imperfect articles in our Encyclopedias, a few papers read before scientific societies, and published only in connection with their voluminous proceedings, and now and then some limited notices of different machines scattered through the pages of our technical periodicals, until the appearance of the book now before us, we have had nothing to meet this want.

The work before us has been prepared by J. Richards, M. E., and consists, in addition to a very full treatise on the construction and operation of wood-working machinery, a history of the origin and progress of such machinery and contains numerous engravings and texts, showing the modern practice and construction employed by prominent engineers in England, France and America.

The plan adopted by the author, as expressed in his preface, is to notice in a general way the leading operations of wood conversion, with the construction and operation of machines in modern use, introducing such rules and treating of such laws as have been fixed by practice and experience, and have come within the knowledge of the writer within an extended experience in designing and constructing both standard and special machines for wood-work. The British *Trade Journal*, in speaking of the work says:--It is a full and intelligent account from the pen of a practical engineer, of the construction and operation of these useful implements, which are every day becoming more of necessity where there is a strain on the ordinary powers of production. The rules here introduced prove the width and depth of the author's experience, both in design and construction.

The illustrations form an important feature of the work, and are as copious as they are well executed. It contains information that cannot fail to be appreciated by all who are especially interested in the construction and operation of wood-working machinery. The author is evidently a practical man, and has his subject well in hand. A valuable extract from this work on "The Band Saw and Band Sawing," will be found on another page.

The work is sold by subscription only. Orders and communications can be addressed to L. H. Berry, 117 North 22d St., Philadelphia. Price, post free, \$6, in cloth, or \$6.75, in morocco.

What to do With Our Boys.

The mechanics of this city, upon whom the onus of the necessity of this question has been charged in certain quarters, have not only denied the soft impeachment, but have come forward as a body, through their representatives, and taken the first practical steps towards a solution of the query. The Mechanics' State Council, after carefully considering the question in its various bearings, have appointed a "Mechanics' Deliberative Assembly," made up of representative men from the various leading industries in the city, who have been asked to come together and devise the best plans for establishing and carrying on labor schools, to which "Our Boys" may have access, and where they may have the opportunity to learn trades, under suitable masters, and thereby employ their time to some present pecuniary advantage as well as fitting themselves for future usefulness.

This movement is most excellent, and opportune, and one which we trust will eventuate in fully solving the difficult problem propounded. The principle of labor schools is not new, but has been carried to a great degree of perfection by the Germans, whose system, with some modifications, might undoubtedly be successfully applied in this city. In order to reach this end successfully it is necessary that the enterprise should be initiated and carried on by men of practical and sound judgment. It is to be hoped that the deliberative assembly, which has been called to consider and devise a plan will so enter upon their work as to bring forth a most perfect scheme for the mental and physical education of those youth of San Francisco, who may be in need of such an opportunity.

Australian Steam Lines.

After waiting for a couple of years to see a permanent steamship service inaugurated between San Francisco and the principal ports by means of a subsidy voted by Congress, the prospect seems farther off than ever. After killing off many schemes, the last one, the Webb subsidy bill has gone the way of all Congressional innocents, and there seems to be but slight hopes of its resuscitation. As a consequence it is now rumored that the regular line is about to be discontinued, and that we are to revert to the old system of sailing vessels, taking from two to four months on the voyage. This would be a calamity of no slight magnitude to our commerce, and it is one which we hope may by all means be averted. Short as has been the existence of the Australian steam lines, it has effected a wonderful change in our commercial relations with Australia. To it may mainly be ascribed the fact that in one year our imports thence have increased seven hundred per cent.; the value alone of the coal imported last year being equal to two-thirds of that of the whole imports of 1871. Previous to the inauguration of steam communication, we were as far removed from Australia, commercially and otherwise, as we are to-day from Eastern Africa, since then the people on both sides of the broad Pacific have begun to know each other's wants and resources, hence, the trade that has sprung up. It is true that a very large proportion of the imports have been introduced in sailing vessels, but it is the regular uninterrupted postal communication which has given birth to the trade so carried on. This trade, if properly encouraged, would continue to develop with the same rapidity, and a counter export trade would spring up still as our merchants began to know the wants of the Australians. The Pacific Coast and the great colonies of the south ought to occupy the same relation to each other that Europe does to the great Republic of the West. There is no doubt that the flow of population to Australia will by and by set in from the Pacific Coast and from Europe—people will prefer a short sea and land route, to three or five months of ocean life round the Cape of Good Hope or Cape Horn. Indications already point that way. An Australian postal convention has decided in favor of carrying mails by way of San Francisco, and population will in time follow the same way. This recommendation and the hope of a subsidy from Australia is the only chance that the present steam line has of being continued. This is not as it should be. If our merchants or capitalists were sufficiently awake to their own interests, they could and ought to organize companies for building steamers, and carrying on Australian trade, as powerful as those being formed for Samana Bay or Navigator Island trade purposes. If our advice was heeded in this matter, our business men would no longer wait for this aid of the Congressional Jupiter, but would arise and put their own shoulders to the wheel.

Leather Belting.

The manufacture of this useful article has become an important branch in our productive interests; therefore, dependent on the East for our supplies in that line, it is no small matter of importance and general economy that our steadily growing manufacturing interests can be supplied with this indispensable auxiliary at their own door.

This state of affairs is attributable, no doubt, to the rapid progress which California has made of late in the leather business generally. Our boundless supplies of the finest and most astringent oak bark, together with our extensive hide market, have attracted to us some of the most skillful tanners of the East and of the old world.

A visit to the factory of H. N. Cook, at 415 Market street, where the belting business is extensively carried on, showed to us a great many interesting things. We noted in process of construction a double belt thirty inches wide for the California Sugar Refinery and two very large double belts for the Pacific Rolling Mills. They are made entirely of center strips from the largest hides, of which these three alone consume over two hundred. The process of stretching, cementing, pressing and rivetting so thoroughly welds and amalgamates the various strips together that they seem in effect to be as though nature had grown them in one continuous strip of the required length.

Mr. Cook informs us that he makes every spring about 100,000 ft. of small sizes for the agricultural trade, for drapers of trowsers and bedders.

We are glad to note the rise and growth of these useful and abiding sources of wealth in our community, and predict that the day is not far distant when our outward bound trains and vessels will be heavier laden than the inward.

MAMMOTH COPPER MINE.—It is stated in a London paper that the Mammoth Copperopolis of Utah have received telegrams from their Superintendent that they are taking out eight tons of ore a day. As this ore is said to yield a profit of \$10 per ton, it would give about \$240,000 a year from the copper, while it is estimated that \$58,000 per annum will be derived from the silver ore as soon as the mill is in operation.

Industries of the Golden City.

Manufacture of Maccaroni, Vermicelli, Etc., in San Francisco.

Considering that we are not a community of Italians, the value of this industry supported by these apparently minor articles of consumption is surprising. Not less than three large and well appointed factories are supported. Of these the largest is that of

Brignardello, Machiavello, & Co.,

Sansone street, who commenced business at their present location in 1856, with five men and one horse power. Since then they have prospered so that they now occupy one of the largest factories in the city, employ eighteen men, and are obliged to have an engine of fifty-horse power to supply the motive power to their machinery. They manufacture all kinds of Maccaroni, Vermicelli and fancy pastes, each of which has an Italian name of its own, to give which would rather embarrass our readers than otherwise. The

Wheat Used

Is of a peculiar kind, hard and glutinous, of a bright yellow color, grown originally in Chili, but most of which is now raised for this firm by farmers in Santa Clara and Livermore Valley, to whom they distribute seed. It is sold at two cents per pound. The seed used being Chilean, has to be continually renewed by importation, for in California, the wheat gradually changes its character, and becomes White Wheat. To

Manufacture This

Into Maccaroni, etc., it is first ground into Farina in a mill on the premises, and the middlings, bran, etc., is separated. The Farina resembles more than anything else, corn meal. It is kneaded in a large trough by a revolving stone, composed of marble, and is thence transferred to a screw press furnished at the bottom with moveable plates, in which boles are punched of the shapes and size desired, and through which the dough is driven. The tubular form is given by a wire fixed in the center of the hole. This done the process of manufacture is complete. For fancy pastes, this firm use a horizontal press, which possesses a cutter that clips off the paste of any length desirable.

Messrs. Tenhorey & Co.,

Mission street, are one of the oldest manufacturers in the city, employing sometimes half a dozen men, and manufacturing largely every description of goods in this line.

Ravenna, Ghirardelli & Co., Battery street, also employ six men, and manufacture proportionately. The

Value of the Manufacture

Yearly is about \$77,000, of which Brignardello, Machiavello, & Co., make \$46,750 worth, and Messrs. Tenhorey & Co. and Ravenna, Ghirardelli & Co. about \$15,000 worth. This represents about 41,000 boxes. There are two principle grades of Maccaroni, which are sold respectively at 12½ and 8 cents per pound. Of all the Maccaroni made in the city, about one-fifth is exported to the Sandwich Islands, Mexico, China and Japan. The total capital invested in the business in San Francisco is \$66,000, and the number of bands employed, 30.

Bullion Product of the United States.

Although the reports of the United States mint, showing the amount of silver and gold deposited for coinage, by no means represent the production of the precious metals of the country, yet the following figures exhibiting the total value deposited in the Philadelphia Mint and branches from 1793 to June 1872, will not prove uninteresting:—

	GOLD.	SILVER.	TOTAL.
California.....	\$642,965,026 09	\$56,423 03	\$643,121,449 12

Total.....	\$836,205,463 50	\$2,065,499 24	\$838,270,962 74

That the foregoing figures convey but an extremely imperfect idea of the quantity and value of the bullion product of the United States, is evident from the fact that the exports of treasure from San Francisco alone, from 1848 to 1868 inclusive, amounted to no less than \$864,495,446, or more than the entire quantity embraced in the mint reports for a period of nearly eighty years. And even the statement of exports above mentioned, from San Francisco, does not include the bullion carried out of the port by passengers, of which no account is given. According to the report of Prof. William P. Blake, one of the commissioners to the Paris Exposition, the approximate total production of the Pacific coast alone, from 1848 to 1868, was, in round numbers, \$961,000,000.

San Jose Woolen Mills.

One of our new manufacturing institutions fast growing into notice and popular favor, is the San José Woolen mills at San José. It was built under the supervision of Judge R. F. Peckham in 1869-70 as a six-set mill, with twenty-four broad Crompton looms and twenty-one hundred spindles.

Its capital stock was originally \$100,000, which before starting was increased to \$200,000.

The Company commenced with three sets of cards in 1870, and ran them until April, 1872, when the extraordinary advance in the price of wools, rendered it prudent for them to suspend operations for a time. Up to that date, they were making shirtings of an excellent quality and cassimeres of a medium coarse grade, noted more for their great wearing properties than for desirability of styles. The mill again started in August last, and since that time has been working at its full capacity, employing 85 hands, using about 30,000 pounds of our best northern wools per month, and manufacturing about \$20,000 worth of blankets, cassimeres, doekings, tweeds, and waterproofs, plain, fancy, and bonecomb flannel. It is under the superintendence of Mr. Arby McDonald, late of the Pioneer Woolen Mills, in this city.

The goods of the San José mills have been improved to such an extent as to excite surprise and admiration from all who see them. Their blankets are unsurpassed in beauty, durability, and weight, and their cassimeres are fast taking the place of English and other foreign goods in this market.

Many of their lighter goods find ready appreciation in Chicago, as is evidenced by the orders we have been shown from that place, and we are informed that they command very satisfactory prices, showing that California can be come an exporter of woolen manufactures, when men who understand the business have taken hold of it.

This company have their depot at 521 Market street, San Francisco, where the above goods may be seen, together with manufactures of underwear, overshirts and pantaloons of every description. This depot is under the management of that popular salesman, John R. Mason, long known to the merchants of our city and of the coast generally.

Silver Peak Mining Company.

A complaint has been filed in the Nineteenth District Court by L. L. Robinson, Henry Malthey, J. P. Kelley, M. T. Tarpey, H. L. Thornton, C. E. Hoffman, C. D. Fitzhugh and D. L. Thomas, against the Silver Peak Mining Company, W. H. Sears, Ira G. Hoyt, Wm. Clive, Samuel McCurdy and George A. Treadwell, which alleges that the above named mine is situated in the Pioche District. That out of the capital stock of 30,000 shares plaintiffs hold 4,500 shares. That at a special meeting of the Trustees of said mine, held December 2, 1872, there were present only J. D. Fry, Sears and Martin—Robinson and Cline being absent—an assessment of 50 cents per share on the capital stock was levied; and that a large number of shares were advertised for sale as delinquent for said assessment. That said assessment was made to pay about \$19,000 for crushing rock in the Condon mill, owned by the defendants. Cline, who was Superintendent of the mill, caused to be sent about 200 tons of low grade rock from the mine to be crushed, at a cost of \$6,557. That on September 26, 1872, Fry, Sears & Cline, Trustees, resolved to issue six company notes, secured by a mortgage in favor of M. W. Fox and Jerry Sullivan, to settle the title to the mine. That the notes and mortgages were executed and delivered to Fox and Sullivan. It is alleged that the demand of Fox and Sullivan was an individual indebtedness of Sears and Cline, and not of the Company. That on January 3, 1873, Fry, Sears and Cline, as Trustees, passed a resolution to pay four of said notes amounting to \$8,000, out of moneys collected for account of said assessment. That on January 31st, Cline presented a claim against the Company for \$4,500, money advanced which was illegally paid, although no vouchers were presented. That on January 31st, the Trustees ordered paid \$6,557 to the Condon mill for crushing rock. It is alleged that said claims are fraudulent, and that the votes of Sears and Cline, interested in said claims, were necessary to order the same paid, and that the Silver Peak Mining Company is insolvent, and unable to pay its debts. Wherefore plaintiffs pray that said assessment be adjudged void; that the proceedings ordering payment for ore crushed by the Condon mill be declared void; that Cline and Sears pay the claim of Fox and Sullivan; that the company be enjoined from paying any of said claims, or the defendants from enforcing their claims. A temporary injunction was granted by Judge Wheeler.

The Raymond & Ely thirty-stamp mill, at Bullionville, changed from a dry to a wet crusher, is said to be working finely.

THIRTY-TWO trains passed over the Virginia and Truckee railroad between Virginia and Carson on the 27th ult.

Mount Diablo Coal Mines.

A correspondent of the Oakland Home Journal, writing from Nortonville, gives the following concerning the local mines at that place:

The cold having driven me to cover, I have bethought me, among other delinquencies, to make good the ones on the correspondence I promised you. Few of your readers are probably aware of the

Extent of the Coal Mining Operations

Carried on at this and other points on Mount Diablo, where, according to Indian tradition, his satanic majesty was wont to hold high carnival. In the present article I will confine myself to the operations at this point, and afterwards walk you over the divide to Somerville, another mining camp two miles distant, but situated on the same coal measures. Coal was originally discovered here about

The Close of 1859,

The original locators being Wm. Colman, David Lewis and Kelson, who took up what was known as the Cumberland claim, on the upper or Clark vein. Shortly afterward Noah Norton, by running a tunnel still further, discovered and located the lower or

Black Diamond Vein

Underlying the Clark vein about 400 feet, passing through an intermediate smaller vein about one foot in thickness. The Clark or upper vein, being about three feet, and the Black Diamond or lower vein about four feet in thickness—all dipping at an angle of twenty-five to thirty degrees, nearly due north, and lying along the northern slope of the mountain.

Erastus Madison afterwards located for Noah Norton another claim on the different veins known as the

Norton Claim,

And situate on southeast quarter of section 15. Various changes were made in the ownership of these different claims, till in 1861 they were incorporated, work regularly commenced and coal shipped to San Francisco market, being first

Hauled by Teams

To New York Landing on the San Joaquin river, distant about six and one-third miles from the mine, and thence by schooners to the city. The mines were purchased by the present Black Diamond Company in 1865 or 1866 and re-incorporated with a nominal capital of \$5,000,000, since which the working facilities have been greatly extended and the products vastly increased, till at the present time the yield is from eight to ten thousand tons per month; for most of which there is steady demand for steam purposes.

From 300 to 350 Men

Are continually engaged in the mines and about fifty on the railroad, or in shops on the upper deck, or about 400 in all. There is pretty steady employment for all, and others in search of employment can generally find it here. So if you find any in want of work, send them along in this direction. Miners are paid from \$1 to \$1.25 per yard for cutting coal, and can average from \$3.50 to \$4 per day, some earning much more. Coal buckers, and common laborers are paid \$2.50 per day. Drivers and timbermen \$3, engineers from \$80 to \$120 per month, and blacksmiths \$100. The company is disbursing about \$30,000 per month for labor, besides large amounts for lumber, machinery and supplies in San Francisco for use here.

RICH ORE.—We are informed that more gold is now being found in the Crown Point than ever before. It is thought that the ore body below the 1300-foot level will run as high or higher in gold than does the Belcher. A lump of ore, weighing about ten pounds, was taken out on the 1300 foot level night before last, which was literally spangled with free gold. The specimen would have assayed at the rate of from \$15,000 to \$20,000 per ton. There is not of course any large body of such ore, but finding such specimens is a good indication that in going down the ore will prove unusually rich in gold. They are now drifting on the 1400-foot level for the purpose of opening out on the vein at that depth. When this shall have been done we may expect to hear of some wonderfully rich ore being found.—*Virg. Enterprise.*

THE IODINE PROCESS for the extraction of the precious metals from sulphurets is in successful practical operation near Liverpool. The sulphurets are ground to a fine powder, and gently ignited with common salt. The mass, when cool, is treated with dilute hydrochloric acid; iodide of potassium is then added to the clear liquid. The precipitate, when dried, contains about six per cent. of silver and gold.

NEW ATLANTIC TELEGRAPH CABLE.—The Great Eastern has now on board 2,567 miles of cable; and the telegraph fleet, consisting of four steamers—the Great Eastern, Hibernia, Edinburg and La Plata—with the new cable on board, which is to be laid between England Halifax and New York, will sail the last week in May. It is expected that the cable will be in working order before the 1st of July.

The 952,055 gross tons of iron ore produced in 1872 in the Lake Superior iron district are valued at \$5,712,330.

THERE were 5,000 tons more of foreign made pig iron imported into New York last year than in 1871.

GOOD WORDS

—FOR THE—

PAIN-KILLER.

We can confidently recommend the Pain-Killer.—[Toronto Baptist.]

It is the most effectual remedy we know of for Aches, Pains, fresh wounds, &c.—[St. John's News, P. Q.]

We advise that every family should have so effectual and speedy a Pain-Killer.—[Amherst N. S. Gazette.]

Our own experience is that a bottle of Pain-Killer is the best Physician a traveler can have.—[Hamilton Spectator.]

For both internal and external application have found it of great value.—[Chris. Era.]

A medicine no family should be without.—[Montreal Transcript.]

Could hardly keep house without it.—[Ed. Voice.]

Should be kept in every house, in readiness for sudden attacks of sickness.—[Chris. Press.]

No article ever obtained such unbounded popularity.—[Salem Observer.]

One of the most reliable specifics of the age.—[Old North State.]

Its power is wonderful and unequalled in relieving the most severe pain.—[Burlington Sentinel.]

An indispensable article in the medicine chest.—[N. Y. Examiner.]

It will recommend itself to all who use it.—[Georgia Enterprise.]

Is extensively used and sought after as a really useful medicine.—[Journal, St. John, N. B.]

No medicine has acquired such a reputation; it has real merit.—[Newport Daily News.]

One of the most useful medicines; have used it and dispensed it for the past twenty years.—[Rev. Wm. Ward, Assam.]

The most valuable medicine now in use.—[Tenn. Organ.]

It is really a valuable medicine, and used by many physicians.—[Boston Traveller.]

We always keep it where we can put our hands on it in the dark, if need be.—[Rev. C. Hubbard, Burnab.]

One of the few articles that are just what they pretend to be.—[Brunswick Telegraph.]

In my mountain travels no medicine is of so universal application as Pain-Killer.—[Rev. M. H. Birby, Burnab.]

I will be glad to furnish prices to any person addressing me on the subject.

HENRY G. HANKS, Manufacturing Chemist,

PAOIFIC CHEMICAL WORKS, SAN FRANCISCO

24v25-4f

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces.—Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Sellers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and sellers for themselves, at the office, 229 Fremont Street, San Francisco

Richardson & Co., Copper Ore Wharves, SWANSEA.

RICHARDSON & Co. have been for thirty years established in Swansea as Agents for the preparation, Sampling, Assaying, and Sale of Copper, Silver, Gold, Lead, Zinc, and all other Ores and Metals, for which they have extensive Warehouses and Wharves under cover, 1,800 feet of Quay Frontage within the Floating Dock, and the most complete Machinery and Appliances. They are also prepared to make advances against Ores in anticipation of realization, and to guarantee all payments when required.

EUCALYPTUS.

The attention of the Medical profession is respectfully called to the following preparation of this new remedial agent. Eucalyptus and its preparations have been found useful in obstinate cases of intermittent and Marsh Fevers, often supplementing the use of Quinine. The paroxysms of Asthma and Catarrhs are greatly controlled, and in various Kidney diseases and Catarrh of the Bladder it seems to act like a specific.

FLUID EXTRACT EUCALYPTUS.

This extract represents in a concentrated form the medicinal effects of the leaves of Eucalyptus Globulus

THE ELIXIR OF EUCALYPTUS.

This compound presents the properties of the leaves in a palatable form and elegant appearance. Dose—One tablespoonful, to be repeated as often as the case demands.

Cigarettes of Eucalyptus Globulus, useful in Asthma, Difficulty of Breathing, Incipient Pleurisy, etc.

Prepared and sold by JAMES G. STEELE & CO., Chemists and Apothecaries,

No. 521 Montgomery St., between Clay and Commercial, San Francisco.

Mansfield Gold Mining Company--Principal place of business, San Francisco, California. Location of works, Kelsey Mining District, El Dorado County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 15th day of February, 1873, an assessment (No. 1) of two and one-half cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the company, room 14, 331 Kearny street.

Any stock upon which this assessment shall remain unpaid on the 25th day of March, 1873, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 18th day of April, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

WM. SMALL, Secretary. mrl

Office--Room 14, 331 Kearny street.

Noonday Silver Mining Company--Location of works, White Pine District, Nevada.

Notice--There are delinquent upon the following described stock, on account of assessment (No. 2) levied on the 15th day of January, 1873, the several amounts set opposite the names of the respective shareholders as follows:

And in accordance with law, and an order of the Board of Directors, made on the 14th day of January, 1873, so many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the company, room 14, 331 Kearny street, on Monday, the 18th day of April, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JOSEPH MAGUIRE, Secy. mrl

Office, Room No. 25, Hayward's Building, 419 California street, San Francisco, California.

Scorpion Silver Mining Company--Location of works, Virginia City, Storey County, Nevada.

Notice is hereby given, that at a meeting of the Directors of said Company, held on the 6th day of February, 1873, an assessment of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the company, room 22, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on the 12th day of March, 1873, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 29th day of April, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Directors. WM. H. MARTIN, Secretary.

Office, 323 Kearny street, Room 22, San Francisco, California. f8-31

The highest price paid for Scrap Iron. 97143

STEVENSON'S PATENT MOULD BOARD AMALGAMATING PAN.

This Pan is far superior to all others in several important particulars. The grinding millers are near the center, requiring less power. The plow-shaped grooves raise the quicksilver with the pulp regularly, with less power, without violence, and with better amalgamating effect, besides admitting of a larger charge. The inclined-shaped housings of the miller-plate openings efficiently force the pulp directly under the millers.

Manufactured at the Golden State Iron Works (Co-operative), 19 First street, S. F.

Where it can be examined and further particulars be learned; or persons may apply to the inventor and patentee, Mr. C. O. STEVENSON, at the Douglas Mine, GOLD HILL, STATE OF NEVADA, where the Pans have long been in constant operation. 15v20-1mr, 1amt

IRON CASTINGS of all descriptions at short notice. All orders punctually executed in time agreed on. Particular attention paid to making superior Shoes and Dies. Among the special castings of this Foundry are the well known CALLAHAN GRATE BAR, of superior merit for burning screenings—all size Bars. STEIGER'S JACK SCREWS, all sizes. Superior, compact and effective Horse Powers, Pumps, Agricultural Castings, Ingot Moulds, Assaying and Refining Retorts and Kettles, and a great variety of other and special castings.

STEIGER & BOLAND Proprietors.

Steiger & Boland are the sole Manufacturers of the Improved Hepburn Roller Pan. The patterns having all the improvements to those Pans, are at the Occidental Foundry, enabling the Establishment to deliver all pans and parts thereof with uniformity, finished in the best style, and at the lowest possible price. Pan Castings furnished the trade, with liberal facilities for erection, &c. All persons are cautioned against making, selling or using these Pans, except through the authorized agents and manufacturers, viz., Steiger & Boland, of the Occidental Foundry, S. F.

22v25-3m

WM. H. HEPBURN,

It has been constantly running for over eight months, and has proved, in competition, to produce a higher percentage of bullion, with less power and with great saving of quicksilver, over any other pan in use. It is simple in construction and operation, and cheaper in first cost and economy in wear.

Miners' Foundry and Machine Works,

CO-OPERATIVE,

First Street, bet. Howard and Folsom, SAN FRANCISCO

Machinery and Castings of all kinds.

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water supplied by pipe A, regulated under this oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 125 First street, S. F. 24v23tf

Repairing done on very Reasonable Terms and in the best manner. No. 32 Fremont street, S. F. 15v23-3m

BURLEIGH ROCK DRILLS

Air Compressors.

The Burleigh Rock Drills, which have stood the test of five years' constant use at the Hoosac Tunnel, and which are now in use in nearly every State in the Union, as well as in Europe and South America, are unequalled in efficiency and economy by any other Drilling Machine. They are of various sizes, and equally well adapted to Tunneling, Shafting, Open Cut or Quarrying, and will drill at ten inches per minute in granite. They are driven by steam above ground. The Burleigh Air Compressor is the best engine yet devised for furnishing the "air motor" for the many purposes to which it is now being used.

They are to be used on the St. Gothard Tunnel, Switzerland; Tunnel 13 miles long. We refer to the following gentlemen and works:

Gen. Newton, U. S. A.....Hell Gate Tunnel, L. I.
Messrs. Shanley.....Hoosac Tunnel, Mass.
J. Dutton Stearns.....Mesquinghoning Tunnel, Pa.
Sidney Dillon.....Fourth Avenue Work, N. Y.
Col. Roehling.....East River Bridge Company, N. Y.

Betts's Capsule Patents.

To prevent infringements, notice is hereby given, that Betts's name is on every Capsule he makes for the principal merchants in England and France, thus enabling vendor, purchaser, and consumer not only to identify the genuineness of the capsule, but likewise the contents of the vessel to which it is applied. The LORD CHANCELLOR, in his judgment, said that the capsules are not, used merely for the purpose of the ornament, but that they are serviceable in protecting the wine from injury and insuring its genuineness. BROWN'S PATENT LAMP.

For Mills and Hydraulic Mining Claims.

One of these Lamps, when placed at a distance of 200
feet from the bank, will light up a bank surface 250 feet
in length and 150 feet high, and to a much better ad-
vantage than any other light heretofore tried, and at an
expense not to exceed five cents per hour. Lamps
furnished at short notice.

[Letter of Recommendation.

Mn. C. B. BROWN—Sir: Your Patent Lamp for light-
ing hydraulic mines, which you sold to me in December
last, has given entire satisfaction, and far exceeds my
expectations, and I think it the best and cheapest light
ever used to light mining claims by night, and am sat-
isfied that I have saved three hundred dollars by the
use of it in the last mining season over pitch or any
other light of the same brilliancy; and I will also say
that if I could not get another lamp, five hundred dol-
lars would not buy it. Yours,

W. D. APLIN.

KNOWLES' PATENT STEAM PUMP.

It has no Cranks or Fly-Wheel, and has no dead points where it will stop, consequently it is always ready to start without using a starting bar, and does not require hand-work to get it past the center. Will always start when the steam cylinder is filled with cold water of condensation.

CENTRAL PACIFIC R. R., OFFICE OF THE GEN'L MASTER MECHANIC, SACRAMENTO, Cal., January 14, 1873.

A. L. FISH, Esq., Agent of the Knowles Steam Pump, San Francisco—Dear Sir: In reply to your inquiry as to the merits of the Knowles Steam Pump, in use upon this road, I will say that it gives me great pleasure to report that they have performed their work well whenever called upon. In no instance have they failed. We have now over 30 of them in use on this road as fire engines, and pumping water for shop and station use. I consider the Knowles Steam Pump the best in use, and prefer it to any other.

Yours truly,

A. J. STEVENS, General Master Mechanic.

Messrs. KNOWLES & SIBLEY, 92 and 94 Liberty street, New York—Gentlemen: In reply to your note of 31st, requesting my opinion of your Steam Pump, etc., as suggested from my experience with them in actual service, I have to state that I have used your pump, and entertain the most favorable opinion of their great merit and usefulness, and for every purpose of which they are superior to any others, and have so recommended and adopted them. They have given complete satisfaction in all cases that have come under my observation.

Yours very respectfully,

WM. W. WOOD.

A. L. FISH, Agent Knowles' Steam Pump—Dear Sir: In answer to your inquiries, we state that the highest award for Steam Pumps at the Eighth or last Mechanics' Fair in San Francisco, was a FIRST PREMIUM and Diploma, awarded to the Knowles Patent Steam Pump, as published in the Official List September 23d, 1871.

W. H. WILLIAMS, Sec'y Board of Managers Eighth Industrial Exhibition, M. I.

Paul's Pulverizing Barrel.

[Written for MINING AND SCIENTIFIC PRESS by A. Blatchly.]

Our engraving represents a view of Paul's Pulverizing Barrel and one of the heads, showing the arrangement of the sides of the barrel and the screens. The ore is fed into the barrel through the trunnion, *D*, from the hopper, *C*, and as soon as it is ground sufficiently fine it passes through the sides, *E E*, which are perforated, and falls on the screens, *H H*. The portion which is ground fine enough passes through the screens and falls down on the outside of the barrel, but what is not as fine passes back into the barrel and is reground.

In the most improved form of this barrel the ore is screened three times before it becomes fit for amalgamating. The inside staves are about a half an inch thick, and are perforated with holes one-fourth of an inch in diameter; outside of these plates is a screen of Russia iron, such as is used in stamp mills, and on the outside of the barrel is a screen of No. 90 wire cloth, through which all of the ore ultimately has to pass.

The advantages of this arrangement are that no extra machinery is required to return the ore to the barrel for regrounding, and the screens are never overloaded as is often the case when fine screens are used. This barrel operates without iron balls, large pieces of quartz being substituted in their stead, so that the grinding is mainly quartz against quartz, reducing the cost of iron and adding to the efficiency of the barrel. As the barrel revolves the ore is carried up on its sides until it begins to roll over and the large pieces pass from the top to the bottom of the ore and strike the ore at the bottom with considerable force, operating like a hammer or stamp, while the mass of finer ore rolls over, grinding like a pau or an arastra.

In this barrel we have both percussion and grinding; after a short time the grinding leaves the particles of ore in a spherical or oval form, and further grinding produces less effect than it did at first, but leaves them in the best form to be reduced by percussion, which leaves them in an angular form which is the best shape for reduction by grinding. This is, perhaps, the only instance where grinding and percussion have been combined in one machine, one assisting the other.

The movement of the ore in the barrel is somewhat singular, being governed by the laws which regulate the movements of the pendulum. When a barrel revolves with sufficient rapidity to keep the ore in constant motion the ore makes a certain number of movements or rotations in a minute, and in a barrel of a given diameter no matter how much the speed is increased the number of movements remains the same. Of course if the barrel revolves rapidly the movements are longer, as when an increase of power is applied to a pendulum, the vibrations are longer, but the number remains the same.

Owing to the centrifugal force, the grinding capacity of the barrel increases in a greater ratio than the number of revolutions of the barrel, so that with twenty revolutions per minute it will do more than double the work than it will with ten. Though this pulverizer has been used for dry crushing only, no doubt it could be applied to wet, and its capacity increased in the same ratio as a stamp mill, which will crush as much again wet as it will dry. A barrel pulverizes, according to the number of revolutions that it makes in a minute and the amount of ore in it.

Either of these conditions can be regulated according to the amount of power available,

which is a great advantage with a variable force like a water power when the work can be adapted to the power. The capacity of large barrels of this construction is enormous. One six feet in length and six feet in diameter will grind thirty tons per day, so that it will pass through a No. 90 wire-cloth by giving a proper speed. Larger ones can be made that will crush from fifty to one hundred tons in twenty-four hours. The merits of this pulverizer are unknown in California, although it is a California invention, and of course it is not appreciated; but for dry crushing it is not surpassed by any machine now in use. Its great advantages over other dry crushers is the facility with which the ore can escape from the machine after it is ground. In this respect it fully equals a wet crushing stamp mill. This barrel is applicable to other purposes of crushing such as druggists require, or for grinding red pepper, etc.

Foundry Notes.

Pacific Iron Works.

At the Pacific Iron Works are to be seen a large pair of hoisting engines, intended for use at the Black Diamond Coal Company's mines. They are nearly completed, and the size will be appreciated when it is known that they will weigh nearly 90 tons. The engines have 24-inch cylinders, with a five-foot stroke. They

PAUL'S PULVERIZING BARREL.

are built on the English plan of hoisting-engines, that is, the drum is placed on the engine-shaft, and is direct, acting without any intermediate gearing. Both engines work together on one shaft. This method entirely does away with the large gear-wheels generally used. The engines are handsomely finished; they are of rather peculiar construction.

At this foundry they are doing considerable work for the Oakland Smelting and Refining Works, an enterprise which will shortly commence operations in Alameda County. They are making refining kettles, furnaces and machinery to go with them. It is stated that these works will be of a substantial and permanent character, and as such will of course be of great benefit to this Coast. In view of making the whole thing a success, the proprietors engaged the services of an experienced Prussian engineer, who is building the works, which will be put up with all the late improvements, so as to do the work as well as it is done abroad.

They have lately turned out at the Pacific Iron Works a No. 7 Root-blower, the largest ever made on this Coast, for the Overman mine. It weighed about 12,000 pounds. They are doing extensive repair-work on the steamer Pelican, putting in a surface-condenser, and overhauling her generally. The job is nearly completed. They made, a short time since, a large set of hoisting works for the Kennedy mine, in Amador county, with boilers, gear, etc.; and another set for the Oneida mine, in the same county. The usual amount of miscellaneous work is being done at the foundry.

A recent addition to the tools of the foundry is a radial drill and an upright boring-mill,

both made at the Niles Work, in Cincinnati. They are both the latest improvements in that kind of machinery.

The Empire Foundry.

Savage & Son, 141 Beale street, is principally employed in manufacturing light castings of all descriptions, particularly stoves. This institution has been established about six years. The pattern of stove made there, which occupies most of their attention, is the "Occident." They also make grates, fenders, stove hollow-ware, cauldrons, kettles and hollow-ware in general.

This firm was the first one who made iron burial caskets, and received a silver medal for them from the Mechanics' Institute at the Fair of 1871. They are made of iron and grained to represent wood. They also make soil pipe of various sizes. Day & Prior, who sell most of this pipe, formerly imported it, but now buy all their pipe from this firm. Among the other light castings made at this foundry are hydrants and sash weights, the latter of which used to be imported. The same is the case with road scrapers, which have ceased to be imported since they began to make them here. Although the foundry is employed principally

on light castings they are prepared to do heavy work also.

The Mining Commissioner's Report for 1871.

We have received the sixth report of the United States Mining Commissioner, which is that of 1871, being the fourth annual report of R. W. Raymond, the present Commissioner. It is entitled "Statistics of Mines and Mining in the States and Territories west of the Rocky Mountains." The volume contains 523 pages, exclusive of the index, which is voluminous. The Commissioner has done very well to get up the report in the manner he has with the small appropriation devoted to that purpose. The sum is only \$10,000, and at least \$25,000 would be required to carry out a comprehensive plan, including resident agents in all the leading districts. The Commissioner says that the amount of money he spent during the year, in the collection of statistics, aside from the work of himself and one assistant, was only \$500. The result of this is that Oregon, Idaho, New Mexico and parts of other States and Territories, are but slightly treated of in this volume, and would have been necessarily ignored altogether if it had not been for contributions which were sent in to the Commissioner by parties interested in certain localities and mining generally.

The chapter on California is the longest and most interesting in the work. It was prepared principally by Mr. W. A. Skidmore, Mr. Raymond's deputy, and contains considerable information, especially concerning the gravel mines. Mr. Skidmore traveled in most of the districts referred to and gathered many interesting items, and he has also drawn liberally

on newspaper correspondence concerning particular localities and subjects, showing that he has paid proper attention to his duties. Some articles have been contributed by well known persons, and taken altogether the chapters bow as much care as any in the book.

The chapter on Nevada is very comprehensive also and is well stored with statistics culled from mining companies' reports, etc., and contributed by parties resident there. The assessor's books also furnish their quota. Montana has about 40 pages devoted to it and Utah about 30 pages. Arizona is covered with six pages and New Mexico with three; 26 pages are devoted to Colorado and nine pages to Wyoming. Metallurgical processes are not discussed to the length they were in the last report. The mining law is given and considerable space devoted to American schools of mining and metallurgy. The "miscellaneous" refers to a few mechanical appliances of mining, some papers on kindred subjects, the hullion product, etc. The work is only sparsely illustrated.

It is to be deplored that a larger appropriation has not been made so that it could have been in the power of the Commissioner to have paid outside parties to write up subjects connected with the mining interest. Another drawback is that very few of the reports are printed and what are issued are distributed among the constituents of Congressmen in the Eastern States where they are not of the slightest use. They can be made the communication for the dissemination of much useful knowledge among the common miners if circulated with half the liberality of the Agricultural Reports, which they are not. The Commissioner even complains that he is unable to send copies of the Report to parties who have voluntarily contributed articles to aid in its completion. The scope of country to which attention should be turned, is large, embracing all the extensive mineral region of the country west of the Rocky Mountains, extending from the borders of British Columbia to the Mexican boundary. It is necessarily out of the power of any one man to direct his personal attention to all the localities within this section of country, and to do so properly it is necessary to have a competent corp of deputies. Under the present appropriation this is impossible. The industry which the Commissioner represents is not only an extensive but a growing one, and, moreover, one in which accuracy of detail is necessary. The latest improvements in its mechanical appliances should be studied and properly tested. The latest methods of working certain classes of ores should be investigated and reported on in detail. Improved systems of working mines, both as regards economy and speed should be examined. All these, and many other points are under the supervision of the Mining Commissioner, but unfortunately he must rely on the statements of outside parties, sometimes interested, or must do without them altogether.

Another great drawback to the usefulness of their Reports is the very unsatisfactory delay in their publications. Here it is the middle of the third month of 1873, and only the advance sheets of the Report of 1871 are to be had. The country makes enough out of the mining industry, in taxes, etc., surely, to give it proper representation. Why cannot these Reports be issued in sufficient numbers to be distributed freely throughout our mining districts? As it is, even very few Superintendents have them, much less the miners themselves. We will, from time to time, make such extracts from Mr. Raymond's Report as will be interesting to our readers, since it is hardly probable that one in one hundred will ever see the Report itself.

CORRESPONDENCE.

Rush Valley Mining District, Utah.

[Written for the MINING AND SCIENTIFIC PRESS.]

Having recently paid a visit of inspection to the mining districts situated in the Oquirrh range of mountains, I have gained some valuable and reliable information about the districts, and more particularly in regard to Rush Valley, which may be interesting to your readers, together with a brief description of the district and its principal mines. This district is not, perhaps, as widely known as many others, but it is second to none in the quantity and quality of its ores, and the natural advantages of its geographical position, which eminently qualify it for becoming the most successful smelting center in the Territory.

Stockton or Rush Valley Mining District is situated on the western slope of the Oquirrh mountains, east of Tooele Valley, Tooele county, Utah Territory, and is distant 35 miles from Salt Lake City, from which it is accessible by a daily line of fine stages, run by Wines & Kimball. The district is about 6 miles long by 5 miles wide, and contains a large number of valuable prospects. It was located in 1864 and the city of Stockton was laid out by General Connor during the same year. The ores are principally argentiferous galena, and carbonate of lead, averaging 60 per cent. lead and from \$25 to \$150 in silver per ton, and for smelting purposes are unsurpassed by the ores of any district in Utah. As I before stated Stockton forms

A Natural Smelting Center

For the following reasons. Owing to its location, ore coming from the adjacent districts in any direction is brought down hill, and is therefore very easily transported there. Charcoal can be obtained at $\frac{1}{2}$ the cost than in the Jordan Valley and other smelting localities. Lime for flux costs \$9 per ton at some of the smelting works in the Territory while in Stockton it can be procured at the moderate price of 75 cents per ton, as it is found in large quantities in the immediate vicinity. Iron for fluxing is also procured in Rush Valley and delivered at the smelting works for \$14 per ton, of precisely as good quality as Wyoming Hematite, furnished in Salt Lake City at from \$16 to \$20 per ton. The immense advantage gained by the reduction in part of these articles needs no remark or comment. But the one great and peculiar advantage of Stockton is that it is the center of a mineral region which contributes all the various ores that can be profitably employed by a smelter, and at a comparatively inconsiderable cost. The silver and lead ores of Dry and East cañons in a calcareous gangue, flux well with the silicious ores of Camp Floyd. Some of the Dry Cañon mines produce argentiferous oxides of iron, which yield a quantity of silver, and render entirely unnecessary the addition of iron ore, which is just as expensive both to obtain and smelt as these ferrous ores of Dry Cañon. The easily smelted ores of the mines in the immediate vicinity of Stockton can also be used as a flux for all the other ores of surrounding districts as their peculiar composition renders their mixture practicable with others in any quantity whatever, as any amount of lead can, by their use, be added to a charge for the furnace, to render the quantity of lead in proper proportion to the other ingredients, without also adding to the charge any detrimental substance which would be necessary if galena were used for that purpose. There are

Two Smelting Works

At Stockton, the Waterman works having two stacks with a capacity of 15 tons each per diem, and the Jacobs & Co. works, with three blast furnaces, having each capacity of 20 tons per diem. The machinery consists of a 45-horse power upright Starkey engine, a 60-horse power boiler, a Dodge crusher with rolls, having a capacity of 100 tons daily and two Sturtevant blowers No. 7. There is also in use a Niagara steam and force pump, and the water is supplied from a tank 60 feet above the building. All the arrangements of this company's works are very convenient and complete.

A run of 30 days at these works have produced the following results which will be found a very

Interesting Item

To others besides those who are miners by profession. Ore used 570 tons, costing \$4,998, taken principally from the mines owned by the company. Cost of smelting \$16.32 per ton—\$9,325. Bullion produced, 139 tons; market value of bullion \$42,172. Freight to market \$1,114, leaving a net profit of \$41,056. The average yield of these furnaces is 83 per cent. of lead in the ores, and 92 per cent. of the amount of silver. Among the

Principal Mines of Rush Valley

Is the Silver King, which has a shaft 300 feet in depth and 150 feet of drifts, showing good bodies of fine ore. The Silver King No. 2 is also a promising mine, and is now more than 60 feet deep. The Vulcan is perhaps the most promising prospect in the camp, and will probably become one of the finest mines in the Territory when fully developed. The vein is three feet wide, and the ore, like a large majority of the Stockton ores, is very easy of reduction, carrying a percentage of lead, and is used as a flux for other ores. It assays from

\$50 to \$60 in silver per ton, and about 40 per cent in lead. Work is being prosecuted actively on this mine, with very encouraging results to the owners. The Quandary is also a very good prospect, having a shaft 150 feet in depth, showing plenty of carbonate and galena ores. The Margaret is 50 feet down and the Muscaten 60 feet, both prospecting well. The following are the names of other well developed mines, which time prevents me from particularizing in regard to the special developments of each. Metropolitan, Legal Tender, Our Fritz, Tucson, Silver Queen, St. Patrick, Bolivia, Pleasant Hill, Defiance, Last Chance, Potomac, Eureka, Great Basin, Mineral Hill, Peabody, Mary Bell, Great Central and Lady Douglass. B. A. M. F.

Salt Lake City, Utah, March 3d, 1873.

Effect of Frost on Iron.

EDS. PRESS:—I am sorry to see such articles in your paper as "Scientific Experiments with Iron," made by M. Carom, wherein it is stated that he tested samples of iron at temperatures of from 0° to 18°, and concludes that iron does not become brittle by cold.

Every wood-chopper, and every man who uses a log chain in a cold, frosty morning, knows better. Axes and chains break like pipe-stems in extreme cold. The reason is this: That in extreme heat or cold the crystals of iron do not retain their original form and consequently do not perfectly adhere; melted iron is fluid with but little adhesive properties; cold iron, to a certain limit, is so much contracted as to impair the original shape of the crystals. The cohesive power of iron is greatest where the original shape of its crystals are maintained. The crystals of iron are oval—elliptical shaped—in which form they adhere most perfectly. Repeated heating and hammering a bar of iron flattens these oval crystals and they then separate in scales, and cleave off, not having sufficient power to adhere when in that shape. Thus successive heatings and hammerings destroy the whole bar.

Rods of iron under extreme tension and vibration, are said by mechanics to have become crystallized, when in fact they have become decrystallized; and, losing their strength, have to be taken down and heated red hot, approximating to a fluid state. The crystals are enabled to resume their original form, in which they adhere most perfectly, and the rod or bar regains its usual strength.

The shafts of steamboat engines, that are under great torsion and tension, and effects of vibration, caused by the motion of the machinery, are decrystallized and easily broken. It is easy to prevent, in great measure, the constant breakage of steamer shafts by doubling or trebling the number of bearings to prevent the vibratory motion, which is the principal cause of breaking, and also by welding up the faggots in a different form.

WM. WAYNE FITCH.

Snison City, Feb. 15th, 1873.

The experiments of Mr. Carom, to which allusion is made above, are by no means received as conclusive as to the effect of iron on cold—although the faith of many in the generally received theory has been severely shaken by the result of these experiments. Carom's experiments with iron rails appear to show that instead of being weaker under the influence of extreme cold, they are actually stronger and the greater number of breakages in winter than in summer, is attributed to the fact that the road-bed is less elastic in winter. This last fact may reconcile experimental deductions with experience in this particular; and may not a similar fact also be made applicable to the breaking of log chains, as cited by our correspondent? May not the breaking in such cases arise from the more sudden, impulsive effort made by cattle in winter, when they are goaded into a heavy pull, than they would exert under the enervating laxative influence of the heat of summer? Again in the breaking of axes in winter, may not such accidents be attributable to the greater rigidity of the frozen wood, rather than to any effect which the frost may have upon the iron of the ax?

There are very many things in regard to the molecular changes of iron which are but little understood. Mr. Roehling states that the most fibrous bar may be broken so as to show a granular and somewhat crystalline fracture, and this without undergoing any molecular change in the texture. "Take," he says, "a fibrous bar, say ten feet long, nip it in the center all round with a cold chisel, then poise the bar upon the short edge of a large anvil and a short piece of iron placed eight or nine inches from the edge on the face of the anvil, and strike a few heavy blows upon the nip so that each blow will cause the bar to rebound and to vibrate intensely, and the result will be a granular and somewhat crystalline fracture. Now take up the two halves and nip them all around again, about one or two inches from the fractured ends, and break them off by easy blows over the round edge of the anvil, and the fiber will appear again." This experiment proves that a break caused by sudden jars and intense vibration may show a granular and even crystalline fracture, without having changed the molecular arrangement of the iron.

Robinson District, Nevada.

[Written for the MINING AND SCIENTIFIC PRESS.]

EDITORS PRESS:—Judging from present appearances Robinson District is destined to attract considerable attention in the near future. The mineral deposits or veins are generally large, sometimes of immense proportions, and although much of the ore is comparatively poor in the precious metals, its great abundance and the facility with which it can be mined, coupled with superior facilities for reduction, will in a great measure compensate for the slight deficiency in the quality.

The district is situated in White Pine county, about 45 miles east of Hamilton, and in the Egan range of mountains. The Hamilton and Schell Creek stage (supposed to be tri-weekly) passes through the camp. The principal town, Mineral City, is pleasantly situated in a narrow cañon known as Robinson Valley. Murray Creek, one of the largest mountain streams of Eastern Nevada, flows through the lower portion of the cañon, and with abundant fall can be made to furnish unlimited water-power for mills and furnaces.

The Mineral Belt

Is about one mile wide and eight miles in length. Its longitudinal axis is east and west, and at right angles to the general course of the mountain range. The formation consists partly of stratified rocks, mountain limestone of the subcarboniferous period, and partly of igneous rocks, (Rhyolite) breaking through granites. The Rhyolite appears to cover quite extensive areas of the granite, and forms most of the low rounded hills in the central and western portion of the district; limestone sometimes forms the capping of the granite hills, but in no case is it found over the igneous rocks. Geologically, this is probably the most recent of the mineral belts found in Eastern Nevada. Mineral veins are found traversing the lower carboniferous rocks in all portions of this district, while in White Pine and other districts they rarely penetrate the Devonian, and are mostly confined to the Silurian.

The eastern portion of the district is situated on both sides of the cañon near the town. The formation is stratified limestone with a north and south strike, and an easterly dip at an angle of 10°. The ore found here is mostly some form of argentiferous and auriferous lead. Some of the veins show considerable copper oxides near the surface.

The Altman Mine

Is the best developed one in this part of the district, and may be taken as a fair representation of its class. It is situated about one-half mile east of Mineral City. It is the property of the Cauton Company. It was formerly worked for iron for fluxing other ores, and was not known to be of any particular value for other purposes until sometime during the past summer; large veins and deposits of carbonate of lead were found traversing the ironstone in every direction. Free gold in paying proportion is found associated with silver, and can be easily washed out of the soft friable lead ores. The seams and deposits of carbonate vary from 1 to 30 feet in thickness, and probably comprise about 1-10 of the whole vein map. The iron contains no silver and but a trace of gold, but the carbonate ore will average about \$45 per ton. The developments consist of one tunnel 400 feet in length, which cuts the vein 200 feet from the surface. Several shafts have been sunk along the line of the lode to depths varying from 60 to 100 feet.

Drifts, aggregating several hundred feet in length, have been extended from the bottom of the shafts in every direction developing a body of ironstone 800 feet in length by 100 feet in thickness traversed by veins of lead ore, and its boundaries have not yet been determined in any direction.

The Hays Mine

Is the next in importance, and is situated 1½ miles west of Mineral City. It is owned in San Francisco. The formation is a stratified silicious limestone, nearly approaching quartzite in composition. The vein courses east and west and dips to the south at an angle of about 70°. As it cuts the stratification both horizontally and vertically it is without doubt a true vein. It is considerably broken and very irregular, varying in thickness from 2 to 7 feet. The main opening is an incline shaft following the lode to a depth of 130 feet from the surface. The ore is considered rich, and several tons of first-class selected for shipment will probably yield something like \$200 per ton. The second-class is worth about \$60 per ton. All the ore found in the mine is very refractory, and I apprehend that the owners will experience considerable difficulty in saving both the gold and silver by any process of milling. The Miami copper mine is situated 2 miles west of the last named. It is opened by a perpendicular shaft 30 feet deep, showing a vein 30 inches thick inclosed in well defined walls of Rhyolite. It is a perpendicular vein with an east and west course. The ore is principally red oxide, containing considerable metallic copper, other ores of copper are found (but with the exception of some black oxide) in too small quantities to be of any commercial importance.

The Weslern

Is situated south of the last, and shows the same kind of ore, but with a larger and stronger vein so far as opened. The Kentucky near the

last is a large vein, and contains considerable silver with copper and iron pyrites. Three miles still further west is the so called

New District.

The formation is principally limestone. The veins are large and have the same character as those found in the eastern portion of the district. Some rich horn silver ore was found in one of the mines in this vicinity about six months ago, and quite a rush was the consequence, but as there was nothing very wonderful the excitement soon subsided. Some of the veins show well and will doubtless eventually prove valuable property.

The Emma has been worked to some extent and shows a body of good ore six feet thick; assays run from \$30 to \$40 per ton. B.

What's the Matter?

[Written for the Press by Almarin B. Paul.]

This is a pertinent question, requiring a volume of figures to fully answer. "What's the matter?" asks the working man, who devotes his time in productive labor, and can give no moments to the study of statistics. He hears of grain products amounting to millions of dollars per annum, unequalled in any land, of tens of millions of gold and silver from our mountain ranges, and yet he is only able to gain a scanty subsistence and sees desolation at almost every tread. "What's the matter?" asks the farmers. My fields produce abundant, and foreign rates for grain, should make me rich, yet I obtain only a scanty reward for my toil. "What's the matter?" asks the miner in the mountains, who any day can plant his foot on riches enough (?)—strata of gold and silver—to supply wealth and comforts to his household, and all about him; and yet there it must lay—for he is bound head, hand and foot, for the want of a little aid in his legitimate enterprise of development.

"What's the matter?" thinks I, as I travel through our mountain towns, and see so much desertion of home-like cottages, and where flowers bloom, the vine twines and the fruit grows neglected. "What's the matter?" Ah, it is serious, and unless the mass step forward to the rescue, the few are to become masters and the many slaves.

The answer to it all may be condensed under four heads, viz:—Dissipation, Speculation, Interest and Monopoly. It is by the two former that the individual sinks himself by his own actions; by the two latter he becomes poor indeed. The former eats his brain, muscle and soul; while the two latter swallow up all his worldly goods.

"But what are you going to do about it?" says one? "Get emigration." Emigration for what? Had we not better make ourselves a prosperous and happy people, first, by building up manufactures, and thus absorbing our now idle and too much dissipated population into productive channels before we urge more into our midst? Why seek to allure emigration when monopolies rule all products, and interest on money precludes the building-up of manufactures? Let us spend our efforts in uprooting the evils we know of, then emigration will follow of its own accord. From the evils which now beset the masses there are only two speedy remedies. 1st: Dissipate less, and work with brain and muscle more. The next is cooperation. Capital combines and becomes a power. Let muscle and brain combine and a greater power at once arises. Welded by reason, it is wealth, as well as strength.

Coöperate in manufactures, and get all the profits. Coöperate in farming and transportation of your headstuffs to their market. Coöperate in mining industries—build your quartz mills yourselves, or associate labor that can do it; mine your ores and mill them in concert, and divide the products. Coöperate and turn this China evil to a profit. You must do it. The poor man has two powers against him, viz: Capital and Chinese labor, while the general progress of the country have several. "Why stand ye all the day idle." The land is bountiful to the hand of industry. Wait no longer for Capital—make it—and while so doing, remedy the other surrounding evils.

With the working man there must be activity. He must plow under this cheap labor element by his activity, industry and frugality or they will plow him under by theirs. Which shall it be? Talk is of no avail. Only in well studied plans of industry is their security and prosperity for us all. It, therefore, behoves every one to do his part in inaugurating a more healthy condition of affairs.

A WORKING man, it is stated, has been, for the first time, elected to the House of Commons of the Canadian Parliament; Wilton, the new member alluded to, is a painter in the shops of the Great Western Railway Company, at Hamilton, Ontario, but he has also been accustomed to devote his spare hours to study, so that he is now one of the most thoroughly educated men in the city where he resides.

BROAD VS. NARROW GAUGE.—It is now thought by some eminent railway engineers that the true advantages of the broad gauge would have been in using rails two or three times heavier than the ordinary rails, and engines in proportion, so as to be able to make a running time that would absolutely defy the competition of the common gauge railroads.

MECHANICAL PROGRESS.

The Band Saw and Ban Sawing.

(Continued.)

In continuing our extract from the very interesting article on "Band Saws" from Richards' treatise on Wood-Working, which we noticed last week, we now come to the subject.

Band Saw Blades.

The blades for hand saws should have what is technically known as spring temper, or if different, a shade above in hardness. If much harder, they are liable to fracture from irregular tension, or concussion of any kind, expensive to sharpen, and difficult to set without breaking the teeth. Rendered softer than this, they are simply worthless, and should have no market value. The amount or degree of temper in a saw blade is quite an obscure matter, one that cannot be determined to any certainty by observation, and hardly by experiment, for although a blade is properly tempered throughout nine-tenths of its length, and certain spots are drawn, as is often the case in grinding, or glazing, the blade is more worthless than if soft throughout.

The purchasers of saws are, therefore, incapable of testing the quality of the saw, and the time of buying must depend upon the good faith of the manufacturers, who usually, and very properly too, are understood as guaranteeing the saw to be of even and good temper, and of fine steel. The working quality, and indeed the whole value of the saw, is in great measure dependent upon the care and skill of the saw maker, of which there exist no evidence, or at least no *prima facie* evidence in the appearance of the blades when finished.

In selecting hand-saw blades a good plan is to roll the ends closely, and see if they will spring back to their first position. The texture of the steel can be examined by breaking a short piece from the end, the difference between coarse granular fracture, and fine lively-looking steel being familiar matter to most mechanics. To determine the straightness of the blade if not joined, unroll it on the floor, and by "sighting it," irregularities are easily detected.

Another most important matter is an exact parallel as to width; the slightest variation in this regard becomes a serious objection to the operation of a saw, producing scratches on the work, irregular action of the teeth, and consequent irregular tension of the blade through its cutting at intervals only.

Any variation of width between the two ends of a blade can be easily detected by lapping them, and placing the points of the teeth on a plane surface, which will show on the back any difference of width, however little it may be.

The pitch, depth, and form of teeth for band saws, is a matter about which there is such a diversity of opinion, that the only safe inference is, that it is either a matter of no great importance, or else not understood. We allude of course to saws for special purposes; for various modifications of the teeth are needed in different cases, and unfortunately the condition that has most to do with the change is continually varying, that is, the depth of the lumber. In considering saw teeth, we have first, pitch (distance between teeth); the inclination on front and back of the tooth (cutting angle); the form of the gullet, as it is termed, for holding the dust; the width of the base of the tooth, so as to give efficient stiffness to retain the "set"; and the kind of set given to the teeth.

It would be supposed that the experience of operating other saws would furnish all that could be learned of band saws, but this does not seem by any means to be the case. The thickness of the blades calls for every minute condition that will tend to keep them true, and to run in line. With a thick circular, or reciprocating saw, the case is different; it can be forced to its work, and made to operate without that nice regard to the condition and form of the teeth that must be observed in band sawing.

For soft wood, a pitch equal to one-half, and a depth equal to one-fifth of the width of the blade, is as near a general rule as can at this time be suggested. For hard wood a closer pitch of one-third the width is better. The gullet or throat under the tooth should in all cases be circular; not only to guard against breaking or checking in the corners, but to prevent the dust from lodging; as with an acute angle it can be carried in quantities on to the wheels. For the front inclination of the teeth, it should be sufficient, so that when the saw is sharp there will be no back thrust on blades; a thing that must in each case be determined by the observation of the operator, and the character of the timber to be cut.

In the matter of setting, it must be determined by the thickness of the blade and character of the wood. In sawing pine, or other soft woods, the teeth can be bent from the base, and will retain their set; but in hard wood or knots this kind of setting does not last long, but soon "comes out," to use a lumberman's expression. Upsetting the teeth is impracticable with thin saws, or at least is very difficult, unless the plates are No. 14 or thicker. The temper besides is, or ought to be, too high in band saws for upsetting. The best plan of setting developed in the writer's experience, in

band sawing, is a quick abrupt bend on the bottom of the tooth by "sharp blows" from a light hammer—setting the steel, as it were, off to one side and raising a kink of scraping edge on the cutting side of the tooth.

It is easy to get a regular or smooth set in this manner, and it requires no special skill to perform it; it is besides sooner done, no gauge being required. The saw is passed over an anvil, with its top bevelled to a proper angle, the bottom edge of the tooth projecting over the bevel, from the sixteenth to one-eighth of an inch, according to the amount of set required.

These remarks upon teeth relate to saws intended for power or positive speed. For scroll sawing or plain hand slitting it is presumed that no information of any interest could be given, and that none is needed.

[To be Continued.]

Conveying Air Through Pipes.

A Supposed Valuable Invention Explained Away.

We sometime since gave a description of a new device for conveying compressed air through pipes for motive power, whereby it was supposed the friction of the air upon the walls of the tube was done away with. The invention may be substantially described as follows:—

If, in a pipe of twelve inches diameter we make at intervals necks of ten inches in diameter, we have an annular space one inch deep around the inner circumference of the pipe. The theory is that the air contained in this space does not move, but remains at rest, and thus presents an air surface to the moving mass of air ten inches in diameter which flows through the necks. As the friction of air on air is less than that of air on iron, he expects to convey power in the shape of compressed air with almost no loss from friction. The invention is claimed by a Mr. Spear, of Boston, and the marvel was endorsed by William A. Goodwin, "city engineer of Portland, and for some years government lighthouse engineer," who had given the invention a practical trial, and, as he supposed a thorough test as follows:

He set a pressure gauge on a reservoir which received compressed air, and when a pressure of 40 lbs. was indicated, opened an orifice in the reservoir so large as to exhaust the effect of the compressor as fast as delivered. The compressor is now working into the reservoir, the orifice blowing off and the gauge stands at 40. Suppose the orifice to be one inch in diameter. Now attach to the same a pipe of one inch in calibre, say 100 feet long. At a point near the outer end of this pipe set a pressure gauge, and the pressure with the pipe wide open, will be found to be something less than 40 lbs. The element of friction has been developed in the pipe. Now take an additional pipe 1 1/4 inches in diameter; on this find the point where a slight diminution of pressure is indicated by the gauge. Just beyond this point insert a ring of one inch orifice in the pipe, giving a shoulder, all around, of 1/2 inch, and the lost pressure will be found to have been restored.

The reservoir has been virtually moved forward to this point. Repeating the operation at the same distance out from this point as from this to the reservoir produces the same result. Each point or section of the pipe charges the succeeding with original force, and it would seem that there can be no limit to the principle.

And now comes the *Engineer and Mining Journal*, and picks the above-described bubble as follows:

It is true that the pressure in the Spear pipe must be more uniform than in other pipes. He obtains this advantage by presenting not less but more friction to the advancing air. At given distances he contracts his pipe so much, that to force a constant quantity of air through the narrow orifice, the pressure has to increase until it equals that at the compressor. This he puts down as a proof that he has saved power? Had he put a cap on the end of his tube the result would have been the same, that is the pressure would have been equal throughout the closed tube. But in this case he would have economized no power, because the flow of the air would be entirely shut off. The difference between this case of a closed tube and that of a Spear tube, which is a partly closed one, is that in one case the power is entirely shut off, and in the other partially so. In the one case the loss of power is complete, in the other it depends upon the degree to which the power has been shut off.

There is certainly nothing new in the fact that pressure can be maintained at a particular point by partly closing up the tube. Other engineers than Mr. Goodwin have, however, been in the habit of considering that greater pressure is obtained by sacrificing to a certain degree the rapidity of flow, or increasing the motive power.

The *Engineer* further refers Mr. Spear to an instance in which the old principle involved in the contraction of pipes has been put in use, and ingeniously so, in a new blowpipe reservoir described in the *Journal*, in which the flow of air is diminished and the pressure increased, so that a constant blast is obtained, and solely by the use of contracted orifices.

A Three Cylinder Engine.

A three cylinder engine is one of the novelties recently described in the *English mechanical journal*. In this engine three cylinders are disposed round the crank shaft at an angle of one hundred and twenty degrees to each other, each cylinder being provided with a deep but light piston, from which a connecting rod is led to the crank common to all. One of the connecting rods has a single eye at the crank end, while the two other rods are forked at that end, the fork of the one being wide enough to take hold of the pin outside the other, so that the center lines of the rods are all on the same plane. The cylinders are all open at their inner ends, and when the engine is at work the steam from the boiler has free access to the central space, so that it tends to force the three pistons outward uniformly. The admission of the steam to, and its release from, the outer ends of these three cylinders is effected by a single revolving slide valve. This valve works against a face at one side of the central chamber, being carried round with the crank shaft. As there is necessarily some throttling in the steam passages, particularly when the engine is running fast, the pressure of the steam at the outer ends of the cylinders never equals that in the central chamber, and hence the pistons are always forced outward. The strain upon the connecting rods being always a tensile one, but varying in amount according to whether the steam is being admitted to or exhausted from the outer ends of the cylinders.

THE INVENTOR OF THE CIRCULAR SAW.—An exchange says: "The invention of the circular saw is generally attributed to Captain Kendall, of Maine, who died a few weeks ago at the age of 89. This is a mistake. The circular saw was invented by Joseph Murray of Mansfield, England, son of an old servant of the Byron family, whom Lord Byron, the poet, often speaks of in his letters as "Old Joe Murray." The first saw of the kind ever made is still shown by his descendants."

AMERICAN VS. ENGLISH ENGINEERING.—American iron bridges are lighter than those of other nations, but their absolute strength is as great, since the weight which is saved is all dead weight, and not necessary to the solidity of the structure. The same difference is displayed here that is seen in our carriages with their slender wheels, as compared with the lumbering, heavy wagons of European construction.

SCIENTIFIC PROGRESS.

The Road to Scientific Success.

It is no longer possible to know everything. A universal scholar will be no longer seen among men. The range of human knowledge has increased so vastly, has swept out and away so far and so fast, that the brain, in its quantity and quality what it may, cannot, in the years commonly given to man, even survey the field. A man, therefore, must make up his mind, if he propose to learn anything, to be content with profound ignorance of a great many other things. It is a bitter thing, perhaps, but is the fact, that a man who would know anything in this century must purchase his knowledge with voluntary and chosen ignorance of a hundred other things.

One must choose his specialty, and devotion and diligence to the subject of his choice is the price he pays for success. It is with doing it as it is with knowing. There is only a certain amount of work in either case. He can not do everything. Nevertheless, everything needs doing. All about him is undone work clamoring for hands. There are two courses before one. To undertake everything, to fret and grieve because one finds this and that undone, and to make spasmodic efforts to do it—this is the way of failure. Resolutely to make up one's mind to let, as far as he is concerned, the most should be undone, stay undone still, to steel one's heart against demands and necessities, to resist all inducements to put forth a single effort, to close one's eyes to it all, and to stick heart, hand, life, and love to the thing a man undertakes and calls his own—that is the way of success. Life is very short, and the single brain and hand, at best, very weak, and there are thousands of things to know and to do. One must choose, and be content with his choice. And so it comes to pass that now at last the measure of a man's learning will be the amount of his voluntary ignorance, the measure of his practical effectiveness the amount of what he is content to leave unattempted.—*Golden Era*.

SCIENTIFIC PRECISIONS.—A curious illustration of the power of scientific precision in the prediction of matters by no means dependent upon mathematical data, is found in a book on "The Coal Question" in England, published more than seven years ago, by Prof. Stanley Jevons, in which he predicted that the coal consumption of England in 1871 would be 117,900,000 tons. In the volume of mineral statistics of Great Britain for 1871, just published, the actual consumption is set down at 117,352,028 tons.

DARWIN AND AGASSIZ.—Mr. Darwin attempts to prove from the variations of animals in domestication, corresponding variations in a natural or wild state; and on these founds his theory of natural selection.

Prof. Agassiz attributed these variations in domestic animals to the intelligence of man, and holds that physical causes have never been known to produce such effects as the intelligent will of man is known to produce.

However greatly the teachings of these savans may differ in their ultimate results, they both agree that man does exert a very great influence on the animals which come under his immediate care; that animals in domestication do vary, and that man, taking advantage of these variations, does by systematic selection, aided by the great law of inheritance, accumulate in certain families or strains of domestic animals, such qualities of economic value as he may desire. These qualities or peculiar traits become, in the course of years, well established characteristics of the family or breed, and are transmitted from one generation to another with almost unerring certainty. In the language of the declaration "we hold these truths to be self-evident," and while from them Mr. Darwin argues his evolution theory, and Prof. Agassiz eulogizes the human intellect, we may confidently trust them as a safe basis from which to work.

A FLAME ORGAN.—At a meeting of a local scientific body lately held at Ipswich, England, an ingenious device was exhibited, which had been constructed to give a practical exhibition of the musical character of the sounds given out by the burning of hydrogen gas in a tube. This fact was made use of in the gas-flame organ exhibited, in which a series of jets, numbering twenty, burning in tubes of different lengths and proportionate sizes, were made to produce a chromatic scale of notes. Each tube was capped with a valve which was opened by means of a connecting rod attached to a digitarium, and thus beautiful chords could be struck, and simple melodies played at the will of the performer. Owing to the tubes being constructed of glass, the action of the flame could be seen. Mr. Goddard, the inventor and constructor of the instrument, played "Home, Sweet Home," and other familiar airs, and his audience were delighted with the correctness and melody of the music. By means of a long tube, the explosion of the gas bubbles which caused the musical notes was rendered visible; for, just as a lighted stick, if whirled round at a greater rate than the eighth of a second, cannot be followed by the eye in its course, but appears as a ring of light, so the rapidity with which the minute gas explosions followed each other could not be perceived by the ear, the effect being that of continuous notes.

BLUE SKY AND WATER.—*Les Mondes* quotes from M. Collas the following remarkable views: He first refers to the blue color exhibited by the pure water of certain lakes, and says that it is due to the therein dissolved or very minutely divided gelatinous silica, quoting as instances the lake of Geneva, the water of the d'Huile, and more particularly the water of a source near the Mont-Dore which water, seven bluish-colored when placed in a white glass decanter. The blue color of the sky is referred by the author to the same causes, viz., very finely divided gelatinous silica (hydrated silica) kept in suspension in the clouds on account of its great lightness. A correspondent in the *Gas Light Journal* thinks these hypotheses have a plentiful lack of probability. Still no more curious chemical questions exist than those connected with the distribution of silica in soils, waters, etc. As to silica in the air, except as mere dust, that seems really beyond credibility.

IRON IN SALT WATER.—At a meeting of the Polytechnic Association of the American Institute, Mr. W. J. McAlpine said: "It is supposed that cast iron oxidizes rapidly in salt water. I have seen in Europe square piles that had been 47 years in salt water, with the weights marked on them, taken up and broken up, and no appreciable loss had taken place. Even the corners seemed sharp and distinct. Here we see water pipes decomposed; and what is the explanation? One kind of iron will decompose and another will not. Where the carbon and the metallic iron are in intimate chemical combination, it will last 100 or 1,000 years, perhaps. The white or gray iron is incombustible, while the soft foundry iron decomposes readily. I have taken up water pipes that I myself laid 30 years ago, and found them not corroded a particle. I have taken up others, which, as you took up a pipe, broke to pieces."

COAL OIL FUEL IN RUSSIA.—Successful experiments are said to have been recently made in Russia in the use of the products of coal oil for fuel for locomotives. The same fuel has also been applied, with reported satisfactory results, in the propulsion of steamboats. The engineers engaged in the experiments report the accomplishment of more work with this fuel than is obtained from the same value in ordinary fuels.

SCIENCE is studied by the observation of facts. But observation is not easy. It requires more memory and a further perspective than most men possess. Experiment, too, is necessary, which is a series of questions put to Nature, and no witness can be found more difficult to examine.

OUR MINING SHAREHOLDERS' DIRECTORY

NOTE.—In the Stock Boards an assessment is delinquent thirty days from the date of levy, exclusive of the date. The dates given in this list are those of the mining offices.

Martin & Co's hydraulic is making the gravel fly from Worth's Hill at a 2:40 rate; quite a face has already been made. The indications are that a good clean-up will be made.

HORSE THIEF.—We have intelligence of a very surprising yield of gold from this mine. A recent cranshing of fifteen tons produced \$750—an average of \$50 per ton. The rock was worked in the anastra connected with the mine. A tunnel 150 ft. in length has been driven on the ledge, which is developing splendidly.

EVERLASTING.—This mine, sometimes called the Scieffard mine, is now turning out each rock as to prove, to the satisfaction of all, its value. The chaft has attained to a depth of 139 ft., with a well-defined lead, of from 9 to 11 ft. in width in the bottom. The rock is very rich, gold being visible to the naked eye in almost

PERTICATO MINE.—Cor. Calaveras Citizen, Mar. 8: The idea of sinking a prospecting shaft on a quartz mine 500 or 600 ft. distant from where the principal deposit of pay-ore is known to exist, and be compelled to drive levee hundreds of feet to intercept the "ore-chimneys" every piece. It is the opinion of experts that the rock now being taken out will mill at least \$40 per ton. That which has already been worked, though quite inferior to that at present obtained, went from \$10 to \$22.50 per ton.

hundreds of feet to intercept the "ore-chimneys," at an expense of thousands of dollars, is idiotic in the extreme. There are several paying "chimneys" in the Petticoat, all of which show a decided northward dip; the most extensive is the one known as the "Whim Shaft" that has yielded seven-eighths of the bullion taken from the mine, and is the farthest north from the present working shaft. In fact, all the pay is north, consequently the deeper the shaft, the

[S. F. Stock and Exchange Board.]

THURSDAY EVENING, March 13, 1873.

This week has been a hard one among the brokers, as mining stocks have been lower and lower day by day for some time, and this week were worse than ever. It does not make any difference whether the mines are dividend paying or not, they are all in the same boat, all extremely low. For instance, the production of the Crown Point and Belcher for the first week of this month if continued will amount in a year to \$2,000,000 more than the whole production of Nevada was last year. Belcher turned out 3,128 tons, averaging \$70 per ton or \$218,750 for the week ending March 7th, and Crown Point produced 3,564 tons, averaging \$68.25 per ton or \$243,611. This combined production is equal to \$24,000,000 per annum. Nevertheless the Stock is much lower proportionately than last year. The *Alta* makes up a table, which shows the shrinkage of Stocks during the past month in 14 mines on the Comstock lode to have been \$6,559,600.

The product of the Crown Point mine for February was \$783,820 and that of the Belcher was \$728,000. The Chollar Potosi turned out \$83,797 during the month. The number of tons of ore worked at the Crown Point mills in February was 12,646 tons, averaging \$61.98. The disbursements were \$259,800; receipts, \$783,820; net profit, \$524,000.

The gross receipts of the Belcher were \$728,000; expenses, \$220,000; net profit, \$508,000. The dividend of \$3 declared on the 5th was increased on the 7th inst., to \$4, payable on the 10th. When the \$3 dividend was declared the receipts for the month were \$654,000; the final clean-up showing \$728,000, it was increased. The dividend therefore amounts to \$416,000, and leaves \$90,000 added to the surplus. Crown Point pays \$3 per share or \$300,000.

On Friday the market was dull and weak, in the morning, but livened up a little in the afternoon, though prices were lower. Gould & Curry fell \$1; Hale & Norcross, \$1; Ophir, \$2; Overman, \$4; Raymond & Ely, \$1. The improved reports of Con. Virginia raised the price \$4.

Saturday, prices were weak and showed a decline at close. Belcher, \$1; Crown Point, \$1; Con. Virginia, \$3; Hale & Norcross, \$7; Jacket, \$6; Savage, \$5; Overman, \$3. Chollar was \$2 higher.

Monday the market was very heavy and prices generally were much lower than on Saturday. As compared with Saturday, Belcher was \$3 lower, selling at \$62 dividend (\$4) off; Crown Point fell \$3; Con. Virginia, 3; Gould & Curry, \$1; Hale & Norcross, \$3; Imperial, 62½ cents; Kentucky, \$1; Meadow Valley, \$1; Ophir, \$7; Savage, \$7. Yellow Jacket was about the same as on Saturday.

Tuesday the downward course continued and prices were extremely low. Wednesday the Stock Market recovered slightly under the reaction caused by low prices and Crown Point and Belcher particularly were in demand. Crown Point was more firm, closing \$91 dis-

dend, \$3, off, being an advance of \$4 over the previous day. Con. Virginia rose \$1.50; Ophir 4; Savage, \$5; Overman, \$5; Hale & Norcross, \$5; Imperial, \$1; Raymond & Ely, \$2.

To-day there was no improvement in the market everything showing a decline, as our Stock tables will show.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned:

California.

ALPINE COUNTY.
GLOBE.—*Alpine Miner*, March 8: Work on the south drift from main tunnel of this mine was resumed this week and is, we understand, to be pushed forward under the chimney known to be in that direction without interruption.

GLANCE SHAFT is now going down below the 75 ft. level—from which drifts were run—in order to test still further the value of depth in discovering improvement in quantity and quality of ore.

CALAVERAS COUNTY.

MosQUITO DISTRICT. — Calaveras *Chronicle*, March 8: Levels are being run in the Dolly Varden at the depth of 100 ft. The vein is large and prospects well. The Cuba, first east extension of the Dolly Varden, shows fine indications equal to the original discovery. New hoisting works will be erected on the main shaft of the Good Hope as soon as practicable. A steam engine will furnish the motive power. The Good Hope mill is crushing ore from the Monte Cristo, at present; some of the ore is very rich. A 10 inch vein has been discovered near the Valentine; the ore is said to be worth \$50 per ton.

WEST POINT DISTRICT.—The ore in bottom of shaft is 20 inches thick and worth in the neighborhood of \$60 per ton. A rich discovery was made this week, a short distance west of those mines. The ore is about 1 ft. thick and every portion of it shows gold pretty lively. A cross drift is being run in the Lone Star to ascertain the width of the vein. Drift in 16 ft. and no footwall to be seen; the ore shows gold freely.

CENTRAL HILL ITEMS.—Work at the Hudson is being pushed forward with vigor. The contractors for sinking the shaft 100 ft. deeper are making great headway. So far the show of having a mine is good. A prospect tunnel is being run on the east side of the hill which will tap the lead at a considerable depth.

Peter Davis' hydraulic claim is in full operation, and at present he is busily piping away at the surface in order to clear a rim of cement which can then be worked off to better advantage. The ground pays moderately well.

and better as they go down, and we are confident that a large amount of rock could be selected from that now being taken out that would go from \$75 to \$100 to the ton.

GRANITE TUNNEL.—The tunnel of this mine is completed to the bed rock of the deep channel. It runs in on an easy incline 150 ft., where a fine bed of gravel is developed. This well undoubtedly prove to be one of the best gravel claims in the county. It has been thoroughly prospected and ascertained to a certainty that there is not only an immense rich gravel bed lying upon the bed rock, from 80 to 150 ft. in depth, but that the bench above it, which is composed of gravel cement, will pay well for working. One great advantage in the mine is that every portion of it can be thoroughly drained at little expense.

ANOTHER SLENDID "FIND."—Placerville Democrat, March 8: Last Thursday our eyes were dazzled by a wonderfully rich display of specimen quartz from Mosquito Cañon. It was found by Carpenter & Co., who brought into town about 300 pounds, of which some specimens, larger than a man's fist contained about equal parts of gold and quartz. One chunk had been completely shattered, and the scores of detached pieces of quartz were held together by bright plates of gold very similar to some of the finest specimens from the Cederberg.

KERN COUNTY.

SUMMER.—Havilah Miner, March 8: This is now one of the best opened mines on the lower coast; it can now be denominated the leading mine of Kern. The 16 stamps are kept in constant action night and day, ponding away at the mine rock; more of which is extracted from the mine than the stamps can crush. The shaft is down about 150 ft., and the vein is gradually enlarging.

NAPA COUNTY.

QUICKSILVER DISCOVERY.—Napa Register, March 8: Mr. J. C. Rice, on last Sunday the 2d inst., discovered a lead of cinnabar near the residence of Mr. Schram, about 5 or 6 miles northwest of St. Helena. Mr. Rice says he first knew of this lead 16 years ago, but has been absent from this part of the country for several years. Some splendid specimens have been brought in from the lead, and a company formed for the purpose of developing the mine.

NEVADA COUNTY.

EMPIRE.—Graess Valley Union, March 7: The Empire is doing well, as we said the other day. For 24 days of last month the mill yielded about \$12,000 with its 20 stamps. This includes sulphurets and clean gold. The gold shipped yesterday was valued at \$11,000.

DABS OF GOLD.—March 12: The Idaho mill's amalgamators were skimmed last Saturday, after the six day's run, and the sum of \$22,000 cleaned up. The batteries were not touched. The Eureka cleaned up \$11,900 for six day's run, with ten stamps, and not \$17,000 as was stated.

PLACER COUNTY.

RICH MINE SOLD.—Placer Herald, March 8: Some weeks ago we announced the discovery of a rich mine near Temperance Flat, some three miles northwest of here. The specimens we examined and found them very rich. Two parallel ledges were located by the discoverers, running for 600 ft. each, and the work of development commenced. Last week some gentlemen from Woodland visited the mine, and early this week thought the whole location for a consideration named in the deed as \$10,000, which includes part of the specimens and an obligation to do \$500 worth of work in the opening of the "Wizard" mine, which lies near the "Miner," as the rich lead is named. Messrs. Bynum, Griffith Lee and Colonel Harper, of Woodland, are purchasers, and will proceed to develop the "Miner" without loss of time. The ledge lies in a district that has been very rich in specimens and coarse gold in the surface diggings, and probably is one of the feeders of those rich surface mines.

SIERRA COUNTY.

PORT WINE.—Cor. of Downieville Messenger, March 8: The claims are all being vigorously worked at Grass Flat, the Slope, the Queen, and this place. When the snow begins to melt, and the boys get to washing their pay dirt that has been accumulating for several months past we may begin to look out for lively times again in northern Sierra.

BALD MOUNTAIN.—This M. Co. have their dump shed full of dirt, but no water to wash. They are working their men on part time to keep along until water comes. There will be a great demand for hands in this county when spring opens.

MINING SUIT.—On the 1st of September, Samuel Tyler, by his attorney, C. M. Tyler, gave Victor Noly a promissory note of that date payable in six months, for \$4,160, with interest; the consideration was the transfer by Noly to Samuel Tyler of the Rocky Bar Quartz Mine. The contract or agreement for the purchase and sale of the mine was subsequently not carried out. Tyler refusing to pay Noly the amount of the note. The latter commenced suit to enforce payment. The defendants filed an answer and cross-complaint, in which the giving of the note is admitted; but they maintain that it is null and void, by reason of fraud and fraudulent representations in obtaining it; that the note was given for and on account of the sale of the Rocky Bar Quartz mine, near Murphy's, in the county of Calaveras, which plaintiff represented to, and assemed the defendants that the mine was rich in mineral-bearing gold rock, which would yield at least \$20 to the ton, and upon these representations the note was given;

that said mine was utterly valueless; that the defendants erected extensive machinery to work the mine, at a cost of \$10,000, and paid \$5,000 in working the mine, and that the yield was not more than \$4 per ton. The plaintiff is now and has been ready to recover back the mine. The answer demands judgment for \$15,000 damages and costs. The case will be tried next Monday.

TUOLUMNE COUNTY.

HIDDEN TREASURES AT CHEROKEE.—Tuolumne Independent, March 8: This mine is situated near the rich district of Cherokee. Their shaft is 40 ft. deep and they have run on the lead north and south 100 ft. The vein is from 8 to 15 inches wide, and mostly in chutes up and down. The ore has been prospected \$40 per ton in assays, and the owner is so well satisfied with his bargain that he has concluded to erect a five stamp portable water mill, which will probably be in operation by the first week in April.

Nevada.

ELY DISTRICT.

RAYMOND & ELY.—Pioche Record, March 2: It is estimated that 100 tons a day are now being delivered for reduction.

CHIEF OF THE HILL.—The main shaft had attained a depth of 167 ft. up to yesterday morning, 150 of which are substantially timbered. A good quantity of \$140 ore is being hoisted daily.

PORTLAND.—By the end of the present month if the Co. meet with no bad luck, connection will be made between the winze and the main shaft at a depth below the surface of 200 ft. The ledge looks well throughout and has every appearance of being a true fissure vein.

STANDARD.—The vein is well defined throughout the entire mine, and has every indication of being permanent. A large quantity of ore has been taken from the bottom of the shaft assaying over \$200 to the ton.

ALPS.—The Alps has been doing nobly. This week it sent out bullion to the amount of \$6,447.35. There is still a large supply of first-class ore at the dump and the usual amount is being hoisted daily.

HORN & HUNT.—Vast quantities of ore continue to be hoisted—much more than, in the present state of the roads, can be hauled to the mill.

AMADOR TUNNEL.—An immense amount of ore is being run through the tunnel, much being of the high-grade class.

PROSPECT.—Usual quantity of ore being hoisted, and a new section being started at the dump-piles, it being impossible to have the ore taken to the mill as fast as brought to the surface.

SILVER PEAK.—T. R. Butler yesterday returned his certificate of two assays, representing high and low-grade ores. The former assays \$100.53, and the latter \$72.20, to the ton.

PACIFIC TUNNEL.—A contract has been let to drive the tunnel in 100 ft. further, and when this is done it is the intention of the company to immediately let another contract.

STAR OF THE UNION.—This ledge continues to show increased vein body and high-grade ore.

MEADOW VALLEY.—Some difficulty has been experienced in getting ore hauled to the mills, and there is a tremendous quantity of ore at the dumps, of all grades.

CHIEF EAST EX.—The ledge has improved much in the bottom of the shaft the last week. There is rich ore on both the foot-wall and the hanging wall, and the vein is widening as sinking progresses.

NEW DISCOVERIES IN BRISTOL DISTRICT.—March 7: Very rich discoveries have been lately made in Bristol district, equaling if not surpassing in assay of ore and width of vein the best mines now in progress of development.

LEXINGTON DISTRICT.—We yesterday had an interview with a miner just down from Lexington District, which is about 80 miles a little east of north from Pioche—the western boundary of Utah running through it, and Sacramento District joining it on the west. Developments have not recently commenced in Lexington District, but the ledges have been sufficiently tested to justify the opinion that it will become an important camp. Shafts are being sunk on seven different claims, about 150 miners being engaged. The ores are of the milling class, carrying a percentage of gold, and with the splendid natural working facilities there at hand, good pay is expected in mining and reducing them. Wood and water are abundant, and there are tracts of good farming land contiguous.

ELKO COUNTY.

SPRUE MOUNTAIN MINES.—Cor. Utah Mining Journal, March 5: The Monarch has a shaft down about 100 ft., the mine looking well, and considerable ore on the dump of very good grade. I think it will average \$80 per ton. In a northerly direction, about 1 mile, is the Badger mine. It has a shaft of 150 ft. of tunnel and a shaft about 75 ft. in depth, showing a large vein or deposit of carbonate and galena ore. They have 150 or 200 tons on the dump, but the grade is not very high—it will probably average \$30 to \$40 per ton.

In an easterly direction, about 1/2 of a mile, is the Latham. This mine is owned by the Ingot Company. They paid \$30,000 for it in October, 1871. They have several hundred ft. of tunnel and a shaft 108 ft. deep. There are immense bodies of ore developed. It is rather low grade, but will average \$25 or \$30 per ton.

About half a mile southeast is the Fourth-of-July mine, which is owned by the same Co., they having purchased it for \$50,000. This mine has been developed by a tunnel about 250 ft. in length. It shows vast bodies of ore in large caves. The ore is of very good grade, and will probably average \$70 per ton.

One-half a mile east of the Latham we come to the Black Forest Mine; the owners have run 4 tunnels for a distance of 150 ft. in length, developing the vein for a distance of 150 ft. in length, each. Each one of these tunnels struck large bodies of rich ore, from 4 to 12 ft. wide. It is the finest-looking ore I have seen on the mountain, and is high grade. The lowest assay they have had is \$86 and up to \$236 per ton. It will probably average \$200 per ton in silver and about 50 per cent. lead. It is considered by experts to be the best mine on the mountain.

HUMBOLDT.

COPPER.—Reese River Revue, March 8: Judge McKenny received a letter from Bolivi District. Mine developments have been made by Messrs. Kellogg & Co., in that country, where they have sunk a shaft 28 ft. deep in iron croppings which appear to be iron, but before reaching the depth above mentioned a splendid vein of copper 4 ft. thick, enclosed in solid walls, developed itself. They were led to sink on these supposed iron croppings by the advice of Mr. George Hearst, who visited the district a couple of months since and gave it as his opinion that the ore would be a splendid copper mine. The result has verified his prophecy.

A RICH STRIKE.—Silver State, March 8: A fine body of ore was struck in the lower level of the Manitowish mine, on last Thursday. The ledge is 5 ft. wide, and the ore principally "shipping," worth from \$300 to \$500 per ton. We have been shown a large-sized specimen of the ore, which is literally coated with native silver.

WASHOE.

HALE & NOBLOESS.—Gold Hill News, March 8: The ore body recently developed by the southeast drift at the 800-ft. level is yielding 60 tons of good milling ore per day, increasing the daily yield to 200 tons.

BELOCH.—Yielding about the same as at last report,

with no change to note in any of the ore-producing levels. The 1,300 ft. level opens out thus far richer and better than any above, and the farther south it is worked the more extensive is the ore-body found to be. The yield for last month was about \$750,000, of which over \$500,000 is clear profit.

GOLD & COPPER.—Sinking the incline has made fair progress during the past week, although the striking of a strong vein of hot water in the bottom has somewhat impeded the work. Prospecting on the other levels continues as usual, with no change of interest to chronicle.

CHOLLAR-POTOSI.—But little ore has been extracted from this mine since our last report, the ore dumps being all not and it being impossible to get the ore hauled to the mills. The main north drift at the fourth station last Tuesday tapped a heavy body of water, which has stopped all work in the drift for the present, and which keeps the pump constantly at work to drain the supply.

SAYAGE.—The daily yield of ore is about 50 tons, the assay value of which is about \$20 per ton, extracted mostly from the old upper works and the 1,300 and 1,400-ft. levels.

SIERRA NEVADA.—Daily yield, 95 tons of good milling ore.

GUVERMAN.—The main west drift at the 1,000-ft. level, has made excellent progress during the week. There is quite an increase of water from the face of the drift, although not enough to impede the progress of the work. The flow of water in the shaft is steadily decreasing.

CON. VICTORIA.—About 25 tons of ore per day are being hoisted from this level, and the indications of a large and permanent body are certainly very flattering.

WOONVILLE.—The winze from the first station is down 20 ft., the pay ore body showing 3 ft. in width of 400 milling ore. The rock at the third station is up 15 ft. the rock working well and the ledge showing 2 ft. in width of good ore. The face of the south drift at the third station is in 102 ft., the ledge showing finely, nearly the whole width of the face in good ore.

MINT.—The ore encountered in the southeast corner of the shaft, at the time the body of water was struck and work stopped a few weeks since, has proved to be a good spur of the main ledge, which the shaft has passed through and is again in porphyry.

YELLOW JACKET.—The main drift east at the 1,500-ft. level has cut through the west wall and considerable quartz is met with, giving low assays. Not far enough in as yet for good ore bodies. At the 1,400-ft. level the main drift is cut, and the drift north of it is in 75 ft. in fine looking quartz, which gives low assays.

CROWN POINT.—Looking finely as usual at all points and keeping up its immense daily yield. The yield of the mine for February was \$733,820 72, of which \$570,000 is estimated to be the net earnings for the month.

NEVADA.—The south drift from the main west tunnel is in 125 ft., having cut through the chimney of ore men, and is in clear rock. This chimney of ore prospects well, bidding fair to develop a fine and permanent body.

NEW YORK CO.—Work was again resumed on this claim last Monday. The heavy body of water in the shaft has been drained and sinking the shaft was resumed last evening.

SILVER CLOUD.—The incline from the bottom of the winze is down to the depth showing well. The drift from the second station is in 15 ft., cutting the ledge—which shows a compact body of good ore.

BUCKEYE.—The average assay of ore being extracted is about \$23 per ton. Rock hard and considerable water to contend with.

BALTIMORE CO.—The main west drift at the 250-ft. station has made good headway during the week, the face of the drift in a mixture of quartz, porphyry and clay.

LEE.—The ore body in this mine is about 8 ft. wide and of a gypsum character, yet rather hard, requiring blasting. It assays all the way from \$50 to \$1,000 per ton, with little or no waste rock.

ALAMO.—Sinking the shaft is making excellent progress, almost the entire size of the shaft being in good ore.

SURMO TUNNEL.—Total length, 3,685 ft. The rock in the face is very hard, but good work is done. Very little water.

GLOBE.—The raise from the main drift is up 60 ft., showing good ore almost the entire distance.

WHITE PINE.

ESGAR SHAFT.—White Pine News, March 8: This shaft has been sunk perpendicularly a distance of 155 ft., and at that depth a vein of ore has been struck, which is being followed east or into the hill. We know from ocular demonstration that the strike is one of no mean importance, and is calculated to show that a vein of ore exists, running parallel with the mines of Eberhardt & Aurora.

EBERHARDT & AURORA CO.—Entering at the old Earl shaft, originally one of the richest prospects on the Hill, we passed through the Earl Chamber, from whence hundreds of tons of rich ore have been extracted, to the Ladies' Chamber, which is 154 ft. from the surface, and discloses a vaulted chamber 64 ft. in height and 100 ft. square. From this remarkable chamber, thousands of tons of rich ore have been excavated and sent to the mills, and the end is not yet. Far from it; as on every hand, above, below, and underneath, can still be seen the choicest quality of paying rock. The extent of the vein or deposit has been developed in the end of this chamber to the width of 100 ft. The line of ore runs due north and south, and from the Earl Chamber, ranges from 10 to 100 ft. in width. Passing from the Ladies' Chamber, we traverse a cut run south 150 ft. in pay ore, some of which we picked out as samples. Mr. Potts informed us that from this chamber he commenced a drift toward the north Aurora shaft, with the intention of making a connection to facilitate the raising of ore to the surface at less expense, and at 150 ft. from the point of departure, ore was struck on the night of the 26th of last month. We saw the strike, and are satisfied of its richness and extent.

NORTH AURORA.—Work has progressed on the main shaft of this mine to a depth of 213 ft., large quantities of ore having been found in the interim, and culminating in the Peerless Chamber. A personal and careful inspection has confirmed us in the belief formerly expressed as to its extent and richness. Passing from this chamber we proceed by way of a tunnel cut in solid limestone, with here and there a bunch of mineral, to the outlet where is situated the ore house, blacksmith shop, and machinery for working the tramway. In the ore house we saw 400 tons of assorted rock, ready for shipment to the mill.

Arizona.

LOCAL MINING OPERATIONS.—Arizona Citizen, March 1: Some months ago D. A. Bennett, Thomas Hughes and others leased the steam works of the Santa Rita Smelter Co., moved them into the Patagonia mountains and we will endeavor to give a report of the progress of their extensive mining business in taking out and smelting ore. This movement was taken in the belief that the Apache would permit work to be continued there, and thus far they have done so. This new start over that way for the first time in over 5 years, emboldened others to explore that region so well known to be full of mineral wealth, until now as per report of Mr. Bennett, more than 200 men are exploring for or developing mines already found there.

A Co. propose to erect reducing works on the upper San Pedro and open up and work a mine near the stream. For this purpose we understand an order has been sent to San Francisco for machinery. Parties are developing several mines about 35 miles to the southwest of Tucson. Judged by return received of samples tested in San Francisco, they are confident of being able to make a profit by shipping the ore to Yuma by wagons and thence by steamer to San Francisco, for sale. This class of ore we are told is abundant.

Some 30 odd miles westward from Tucson 3 men are

working on mines with very encouraging prospects. Considerable of the ore contains enough gold to enable a man to make from \$2 to \$2.50 per day with a hand mortar, and that they intend to construct arrastras very soon. Water seems to be plentiful within a few feet of the surface and some springs are near by, and the country about is in excellent pasturage. A vein of white marble is also reported to extend for many miles in this section.

QUARTZ MINING.—Arizona Miner, March 1: The Del Pasco mill and arrastra, Mr. Pointer's arrastra, on Lynx Creek, Mr. Cullumber's small mill at Walnut Grove and many other "machines" are now running or soon will be so that we confidently look for a yield of from \$3,000 to \$4,000 per day from this on.

Parties are plying in their hydraulic claims on lower Lynx Creek, taking out not less than \$200 per day.

YUMA COUNTY.—Work on the Constantia will soon be renewed, under a new Superintendent. The mill is one of the best on the coast.

Idaho.

RED JACKET.—Owyhee Avalanche, Feb. 22: There is now a splendid exhibit about the rich strike in this mine. After running the adit level 600 ft. they came apparently to the end of the vein, but drifting about 20 ft. west, they struck it again, and are now running north, with about 250 ft. to run in order to reach the north shaft which is 90 ft. deep. This will give a continuous body of ore, 850 ft. in length, with 250 ft. of backs. This rich body of ore contains a 34-vein, and is now 20 ft. wide, increasing in richness and size as they go down. It is wonderful to behold. By the light of a candle, free gold and pure silver can be seen sparkling through it everywhere. Mr. Miller has made a milling test of 30 pounds of the ore, which yielded at the rate of \$1,500 per ton.

IDA ELK MOUNT.—The prospects of this mine are favorable. The drift is in about 60 ft. on a vein from 4 to 5 ft. in width of high grade ore.

GOLDEN CHARIOT.—The prospects of this mine are encouraging. At present the mine is yielding about 8 tons of ore per day.

ILLINOIS CENTRAL.—This mine continues to yield a rich quality of ore.

BELLE PECK.—Mr. Peck is still prospecting his mine favorable results. He has proved the rich chimney to extend over 100 ft. in length, and has 25 tons of ore on the dump which he thinks will mill upwards of \$100 per ton.

WAR EAGLE.—Nothing doing in this mine at present.

MARSHALL.—Richer than ever in the 6th level south, and shipping a large amount of ore to the land, and striking it richer and more extensive than ever.

Montana.

GOLD CANON.—Cor. New North West, Feb. 22: There are two companies working here this winter, but with result is not known. Jones & Co., struck a very rich deposit of gravel in the claim, from 12 to 15 ft. thick, which will pay from \$25 to \$50 per day to the land, and there is ground enough to last them for a number of years. Williams & Co., are taking out pay dirt with very flattering prospects.

BUTTE MINES.—March 1: A gentleman from Butte has handed us some splendid samples of ore which Mr. Gilchrist is now taking out of the Parrott lead, the rock and crevice showing better than ever before. The lead which was struck at one place to 4 inches has widened out and continues to widen regularly at the depth of 110 ft. to which depth the shaft is now sunk. The samples handed us are very rich in born silver and copper. Our informant says the bottom of the shaft for ten feet glitters with silver as the light is passed along it. Six men are at work in the shaft, but no working at once disd—

Some parties are getting out ore on the Moscow, but the snow which is 3 ft. deep on the hills above Butte, prevents considerable representation and development that would otherwise be done.

Utah.

RIOB STRIKE.—Utah Mining Journal, March 6: We have just been shown a five-ounce specimen of horn silver taken from the Lion Hill, Gphir District, which assayed \$27,000 to the ton. It was a beauty. The shaft in the mine is down about 50 ft. and a rich 4 ft. lead is opened. \$300,000 has already been offered and refused.

New Incorporations.

The following companies have filed certificates of incorporation at the County Clerk's Office in this city:

BELLE ALLEN MINING CO.—March 8. Capital, \$300,000. Object, to carry on business in Sierra county, California.

SPRING VALLEY CANAL AND MINING CO.—March 8. This company filed a certificate of increase of stock from \$600,000, in 1,200 shares of \$500 each, to \$4,000,000, in 40,000 shares of \$100 each. The present assets of the company are \$515,000 in gold coin, and its debts are \$86,000.

WISLA STAR CONSOLIDATED MILL AND MINING CO.—March 8. Capital, \$500,000. Object, to carry on a general mining and milling business in East Tintic District, Juab county, Utah Territory.

Articles of incorporation of the Santa Rosa (Sonoma county) Savings Bank were filed in the office of the Secretary of State at Sacramento March 10th. Capital, \$100,000.

THE RISING STAR CONSOLIDATED MILL AND MINING COMPANY.—March 8. Location: East Tintic Mining District, Juab county, Utah. Capital, \$500,000, divided into 50,000 shares. Trustees: A. Albertson, J. M. Case, W. LeRoy, Thomas Rogers, G. A. Miller, E. J. Elzy, W. F. Sherwood.

THE SILVER PEAK MINING CO. have elected the following Trustees: A. J. Bryant, C. W. Rand, O. E. Elliott, W. H. Sears and J. W. Martin.

The annual meeting of the Almaden Quicksilver Mining Company took place in New York on the 26th ultimo. The total product for 1872 was 18,572 flasks. During the first three months this product was sold under a previous contract for \$31 per flask, and subsequently at \$50.50, the total realizing \$937,886, while the net profits for the year, including rents, were \$451,759. The expenses of the year embraced \$100,000 for tunneling and prospecting. There is no floating debt, and the assets include \$480,000 in cash and quicksilver and supplies to the value of \$115,000. The following persons were elected Directors for the ensuing year: Daniel Drew (President), James S. Thayer, James H. Banker, A. B. Baylis, E. D. Stanton, E. N. Robinson (Treasurer), Eugene Kelly, Edwin Hoyt, George G. Fride, Ludlow Patton and James D. Smith. David Mahoney was chosen Secretary.

THE WOODBURN WHEEL FACTORY at Indianapolis, the largest establishment of its kind in the United States, was destroyed by fire on the 12th inst.

A Chapter on Rats.

Whosoever man goes the rat follows or accompanies him. Town or country are equally agreeable to him. He is a most enterprising traveler, and is continually passing from one country to another. Scarcely a ship leaves a port, without taking on board its complement of rats for the voyage. It is thus that this destructive little rodent has distributed himself over the entire civilized world. These remarks apply more particularly to the brown or Norway rat.

Although called the Norway rat, this variety of rodents did not originate in that country, but came from the warm regions of Central Asia. It seems to have taken up its migratory habits about the time of the revival of commerce, near the year 1700. It found its way into southeastern Europe in the early part of that century, where, after multiplying largely, it commenced a northward march into Russia, crossing the Volga in large troops. It reached England in 1730, and France in 1750.

In its march through Europe it drove before it or exterminated the black rat—the native house rat of that continent. In 1775 it "took ship" and crossed the ocean to America, whither it had been preceded by the black rat a few years before; and here also it soon exterminated its black congener, and has reigned since master of the cellar and the sewer.

In unsettled countries the black rat is wild and lives in the woods; but does not multiply rapidly; while in civilized countries it generally avoids the fields and woods, conforms itself to the customs of civilization—dwelling in artificial homes. Both these varieties enter your house, a tenant at will—their will, not yours—shares in your food, and holds nightly revels with the belles of rat-land, in the innermost recesses of your dwelling. Their sagacity in securing food and avoiding detection is most wonderful. In this respect they approach nearer to certain classes of the human species than any other animals.

The black rat is much more timid than the brown, and dislikes burrowing. He prefers the upper parts of dwellings to cellars or any low, filthy places. He is the aristocrat of the rat tribe; is less gregarious than others, and travels in small, select parties. Of course he is not a fighting character. On the contrary, the brown rat is very ferocious, fights and travels in large companies, and pursues war to the death against his enemies.

Our illustration presents a view of a lively combat between a party of brown and black rats—the latter having evidently been surprised at a convivial entertainment in the corn crib of some Western farmer. Their mode of battle and quick dispatch has been vividly portrayed by our artist.

The black rat never found its way to California—his race, on this continent, was cut short by the break in human habitations in the "far West" of the Atlantic States, where his "forlorn hope," as an advance guard, was overtaken by the vindictive pursuit of his ancient enemy.

The early residents of San Francisco say that the old Mission and the early dwellings in the city proper, were occupied by a variety of white rats; but as no specimens have ever been noticed by our scientists, the inference is that the "white rats" were nothing more than a variety of the brown, which, at that time, had been but sparsely introduced by transient

ships coming to this Coast with supplies for the early Jesuit missionary settlements, and stopping to gather hides for a return cargo. This supposition gathers strength from the fact that the brown rat is prone to exhibit this variation of color, whenever it becomes isolated, or for any reason ceases to multiply rapidly—a condition that was well fulfilled during the period anterior to the advent of the gold-hunters, when civilized habitations were so scarce here, and because that aristocratic variety of the rat family is extremely loth to remain with dwellers in huts.

The predominating native rat on this Coast is the *Mus Californicus*,—commonly known as the short-tailed rat,—a variety of the wood rat, which, from the disinclination of the brown rat to follow into outlying bushes or woods, never has, and probably never will be exterminated by the new-comer. This rat, consequently, is still found in great abundance, especially all along the Coast Range, both in mountain and valley, where it builds mounds of sticks, leaves, etc., often ten feet in height and twenty in diameter at the base. These mounds serve as convenient retreats for the rodents from their natural enemies, and their elevation above the surface of the earth fur-

Silk in the United States.

It is gratifying to learn that one of the most important manufacturing interests of the more industrial nations of Europe, is also steadily and advantageously gaining ground in our own country; we allude to the manufacture of silken goods. A cotemporary chronicles the following facts and figures in relation thereto, but omits to tell us that the raw silk from which these fabrics are wrought, are obtained almost entirely from foreign countries where cheap labor is the rule.

The silk interest has grown in the last few years much beyond what has been generally supposed. A report issued by the silk manufacturers of America states that the growth of this production is steadily increasing. Within a decade it has sprung from an insignificant and unpromising experiment, and now bids fair to become one of the lucrative branches of our varied industry.

There is said to be at this time a capital of over \$30,000,000 invested in the business in this country, against less than \$3,000,000 in 1860. Sixteen thousand operatives are employed, earning \$8,000,000 per annum, and weaving between \$30,000,000 and \$40,000,000

Singular Discovery of Gold.

A gentleman informs the Nevada Transcript of a most singular discovery of a piece of gold, at Red Hill, about a mile from this city. He says one of the owners of the land was walking by a piece of ground, a few days ago, where the top dirt had been washed off to the depth of about five feet, and saw something shining. He went to the spot, and ascertaining it was gold, took out a piece weighing about three ounces. Informing his partner of the discovery, they supplied themselves with tools, and returned to the spot where the three-ounce specimen was found, and proceeded to clear the clay away for a distance of two and a half feet in length and nearly two feet in width, which was as far as the gold could be traced. The gold lay nearly flat the whole of this distance and on the bed rock. If it had been melted and poured out it could not have been so nicely laid as it was there. Some portions of it was as thin as a wafer, and none of it thicker than a twenty-dollar gold piece. Our informant says if it had been taken out as he saw it, it would have been the most beautiful specimen ever exhibited in the world. The owners on seeing the sight became excited and anxious to ascertain the result of their discovery commenced picking it out every way, thus spoiling the beautiful specimen. Its appearance seemed to indicate, at first sight; that it was a massive boulder of gold, and on the surface it looked as though there was a block of gold worth millions of dollars. They dug it out in pieces of various sizes, and the total value of the gold was \$3,000. The most singular part of it was, there was no quartz in it, although the hill is full of quartz.

Some people may think that this was a "salting process," in order to effect a sale for a large sum of money. But we know that such is not the case, as the ground in that locality is not for sale. Furthermore, many such pockets have been found on Red Hill, one of which, discovered many years ago, yielded over \$7,000, and others varying from \$50 to \$1,000. As a rule, these "pocket claims" are not remunerative, from the fact that when a "pocket" is struck, miner's will often spend twice as much as the amount taken out in trying to find another, and then be disappointed; and Red Hill is not an exception. Large amounts of money have been taken out of this hill, and a great deal been spent in prospecting. But we think

the time not far distant when it will be demonstrated that one of the richest quartz ledges in the country runs through Red Hill, which when developed, will add greatly to the wealth of Nevada county. All through the hill floating quartz and spurs may be found, and as the famous Schmitt ledge is close to and runs in that direction, there is good reason for the belief that Red Hill will yet be made to unseal her hidden treasures, and reward the faithful prospector for his untiring energy.

ASSAYING LEAD ORES.—Previous to reducing the galena or other lead ore to the metallic state, A. Mascazzini converts the lead present in the ore into sulphate, by igniting it in a porcelain crucible with sulphate of ammonia, after which the ore is treated in the usual manner. The flux preferred by the author is that recommended by Plattner, consisting of 13 parts of carbonate of potassa; 10 of dry carbonate of soda; 5 of previously fused borax; and five of well dried starch.

ANTI-SEA-SICK CABINS.—The famous Bessemer ship has encountered a rival in the floating cabin devised by a Russian. The construction is very much the same as that of the Bessemer but the cabin instead of being attached to a pivot, literally floats amidships between the engines. The invention has been tested by the Grand Duke Constantine, and is deemed successful.

SOUTH BEND, Indiana, claims 150 industrial establishments, employing 2,100 workmen, and turning out an annual product of \$5,000,000, or \$500 to each inhabitant of the town. Its buildings erected in 1872 cost \$1,300,000.

THE BATTLE OF THE RATS.

nishes a safe retreat in case of overflow.

The omnipresent brown rat, however, has driven this native well out of all the city and village sites, and, for the last two decades, has made itself unpleasantly abundant, wherever, throughout the Pacific Coast, the Anglo Saxon has planted his homestead.

NITRATE OF SODA.—The following item comes from South America: In view of the vast national importance of the new law limiting the production of nitrate of soda and making the Government the sole exporter of that most valuable article, the following data will be found interesting, as showing the steady increase of the demand:

In 1870, 2,500,000 quintals of nitrate were shipped from Peruvian ports to all markets abroad.

In 1871, this figure was increased to 3,000,000 quintals, and in 1872 reached the very respectable sum of 4,420,000 quintals.

PHILADELPHIA manufacturers, employing in the aggregate 10,000 persons, are, the *Inquirer* says, preparing to abandon Philadelphia, and carry on their business in Delaware, in order to be under lighter taxation. The proprietors of the Pascal Iron Works have already done so.

MINING matters at Little Cottonwood Cañon, Utah, are moving ahead in good shape, and there is every prospect for a big yield of ore next season, the principal work doing at present being preparatory.

THE Seattle Coal Company is now shipping 150 tons of coal daily.

worth of silk goods in a year. The report assigns as one of the drawbacks to a more speedy development, the fact that the California raw silk must all be sent to Europe to be reeled, the improved machinery necessary for that purpose not having, strangely enough, found its way as yet to this country. The American silks are universally admired, both in this country and in Europe, and when our facilities are matured will be able to compete with the world.

RAILWAYS IN SOUTH AMERICA.—The railways from Arequipa to the large interior cities of Cuzco and Puno are being pushed forward with much energy, the natural obstructions to be overcome rendering the labor one of extreme difficulty. Once on the level plateau running from Puno to within sixty miles of Arequipa, and that point is almost reached, the advance will be remarkably rapid. The line from Obimbote to Huzraz, considered by many well acquainted with the resources of the country as the most important railroad in Peru, has some thirty-six miles now ready for ironing.

NEW MAIL STEAMER.—The Pacific Mail Company's new iron steamer "Colima," 3,250 tons burden, was successfully launched from Rooche's ship-yard, at Chester, (Pa.) on the 6th inst. There are four others now on the stocks for the same company, of which two have a tonnage of 5,000 tons each.

COAL and quicksilver are claimed to exist in Mendocino county in the neighborhood of Ukiah.

USEFUL INFORMATION.

Relative Weights of the Sexes.

Somebody who has been "studying our weights" reports that, upon the average, boys, at birth, weigh a little more and girls a little less than six pounds and a half. For the first twelve years the two sexes continue nearly equal in weight, but beyond that time males acquire a decided preponderance. Thus, young men of twenty average one hundred and forty-three pounds each, while young women of twenty average one hundred and twenty pounds. Men reach their average bulk at about thirty-five, when their average is about one hundred and fifty-two pounds; but women slowly increase in weight until fifty, when their average is about one hundred and twenty-nine pounds. Taking men and women together, their weight, at full growth, averages about twenty times as heavy as they were on the first day of their existence. Men range from one hundred and eight to two hundred and twenty pounds (the Tichborns claimant weighs about three hundred and sixty pounds) and women from eighty-eight to two hundred and seven pounds. The actual weight of human nature, taking the average of all ages and conditions—nobles, clergy, tinkers, tailors, maidens, boys, girls and babies, all included—is very nearly one hundred pounds. These figures are given in avoidupois weight; but the advocates of the superiority of women might make a nice point by introducing this rule that women be weighed by Troy weight—like other jewels—and men by avoidupois. The figures would then stand—young men of twenty, one hundred and forty-three pounds each; young women of twenty, one hundred and sixty pounds, and so on.

DANGER FROM MATCHES DIMINISHED.—The danger from the use of matches arises from the fact that the head, or a portion containing the head of the match breaks off in the act of taking fire, falls upon the dress, and sets it in a blaze. But it is because the match when drawn across a rough surface in order to ignite it is always drawn toward the body, that the broken, blazing head takes that direction and so falls upon the dress. Probably ninety-nine persons in a hundred, when lighting a match, pull it towards the body, and not from it. The reason undoubtedly is, that the motion towards the body is from our anatomical structure, a pulling motion, which is stronger, and therefore easier than a motion from the body, which is a pushing motion. But whatever the cause, the fact is that most people in lighting matches, pull them towards the body; whereas, if they pulled them from the body, the head of the match, if it broke off, would almost always take the same direction from the body and the dress. We owe this to the observation of a friend, who once set his night gown on fire with a match drawn towards the body, and who was thus led to study the philosophy of the subject. He teaches his children religiously, to draw matches in a direction from the body; and if this rule were universally adopted, many useful lives would be saved every year. The suggestion is so obvious; so simple, and so truthful, that it ought to be published everywhere, where people who read can see it.

ZOPISSA.—An English officer has discovered the means of circumventing time in a transparent varnish which he calls Zopissa. It is used on exposed surfaces, filling the pores, making a surface so close that no water can penetrate it. It is also remarkably insensible to heat, asbestos being less destructible. As a varnish it equals shellac, copal, gum or pumice stone. In addition it is an excellent cement, uniting porcelain glass, building stone, and iron, while it unites wood, and is delicate enough to seal an envelope. The *Art Journal* thinks this is the substance with which the ancient Egyptians used to embalm their dead and preserve their works of art. It is a fact that, while the frescoes of Rome are becoming dim, the Egyptian mural paintings are fresh and pure. The paintings of Egypt have been exposed to a gas jet, but without any evil effects. If Zopissa even approaches this quality of endurance, which we have hitherto conceded to have been one of the "lost arts," its value will be unmistakable.

PETROLEUM FOR BOOTS.—Dr. Van der Weyde tells us petroleum is decidedly very injurious to leather; it shrinks the leather, so that boots dressed with it become finally so small that you can no more wear them. Leather pump-valves cannot be used for petroleum pumps, as they become so shrivelled up as soon not to fit any more, and cause the pumps to leak. If the manufacturers soaked only the pegs in petroleum, before putting them in, he thinks it might be beneficial.

TEA IN INDIA.—The experiment of growing tea in India is proving quite successful. In 1862 the crop was estimated at 1,000,000 pounds; in 1871, at something over 20,000,000. It is claimed that India can now compete with China in producing teas of the best quality.

A SANDPAPERING MACHINE.—The *Scientific American* thus directs to make a sandpapering machine. Use canvas belts strongly sewed together at the ends. The threads may be so tied together as to leave the face on emery side of belt perfectly smooth and level. Size the belt with a coating of thin glue and then let it dry. Hand the belt over two pulleys so that it can be easily turned. Use the last glue, of about the consistency for glueing wood; put it on hot with a brush, sifting the sand or emery on at once. Go round the belt as quickly as possible, then lay it on a smooth plank, and roll the sand or emery into the glue as hard as possible, (an iron pulley, loose on a mandrel, is best;) then hang up the belt to dry.

ABSENCE OF FEAR IN WILD ANIMALS.—In a letter from the Galapagos Islands the writer remarks the wonderful tameness of all the wild creatures that have hitherto been unmolested. The seals, he says, seemed to be fond of crawling under bushes, just above high-water mark, and sleeping two or three in a place. Under one bush lay a mother and her cubs, and so fearless was the old one, that when one of the officers held a piece of cracker to her nose she smelled at it as fearlessly as if she had been a pet dog. The tameness of many of the birds was also surprising, for the fingers might be put within half an inch of little yellow-birds, and within six inches of mocking-birds.—*Scribner's*.

THE SEXES.—There are more males than females born by 4 per cent. At the age of 20 there are more females than males. At the age of 40 the preponderance is again on the other side, and there are more males than females. At 70 the sexes are again even. Between 70 and 100 years there are more women than men, or an excess of 5 per cent. The mortality of woman is greatest between the ages of 20 and 40. After 40 years of age the probabilities of longevity, as is shown, are far greater for females than for males.—*Phrenological Journal*.

EGGS IN CASE OF TROUBLE.—Eggs are useful for many purposes besides food and for hatching. If you get a fish hove in your throat, and sticking fast there, swallow an egg raw and it will be almost sure to carry down a bone easily and certainly. There is another fact touching eggs which will be well to remember. When, as sometimes by accident, corrosive sublimate is swallowed, the white of one or two eggs will neutralize the poison, and change the effect to that of a dose of calomel.

STREET MAKING IN LONDON.—During last year two hundred and twenty-six new streets have been opened in London, with an aggregate length of thirty-eight and a half miles. During the past ten years one hundred and fifty thousand houses have been built in London, and new streets opened involving a length of six hundred and thirty-five miles. As large a number of houses are now built in London, annually, as are comprised in the entire city of San Francisco.

THE OIL FIELDS COMPARATIVELY EXHAUSTLESS.—It appears that the first oil field around Titusville, is again coming into prominence. Territory that was long since abandoned and thought to be worthless, promises to become as prolific as any in the whole oil region. Several wells recently put down in this territory flowed from 100 to 500 bbls. per day, and promise to maintain a yield equal to if not larger than those in the Butler district.

"ADAM'S APPLE," so called, is an enlarged section of the trachea or windpipe. It is larger in men than in women, and it is possible that the gruffness of the voice may bear some relation to that development. The name is said to have been given because Eve ate the apple and Adam swallowed the core, which stuck in his throat. But as food does not go down that pipe at all, we may presume that it is not the cause of it.

TO CLEAN GOLD CHAINS.—Put the chain in a small glass bottle with warm water, a little tooth powder and some soap. Cork the bottle and shake it for a minute violently. The friction against the glass polishes the gold, and the soap and chalk extricate every particle of grease and dirt from the interstices of a chain of the most intricate pattern; rinse it in clear cold water, wipe with a towel, and the polish will surprise you.

SMOKELESS POWDER.—Smokeless gunpowder is now manufactured in England named after the inventor, Schultze's Wood-Powder. It can be made cheaply; there is less danger in its manufacture, and gives more penetration than our black gunpowder. Such, at least, is the statement. We have been unable to learn whether it has been introduced into the United States.

A GOOD TRADE is always a comfortable companion to travel with, a something that a man can fall back upon in the time of need, and yet it does not preclude him from entering upon some profession, if his inclinations or genius develop the proper capacity. In fact, our most successful business men in almost every capacity are from the workshops and farms.

FLY POISON PAPER is usually made by impregnating common paper with a solution of equal parts of sugar and arseniate of soda.

GOOD HEALTH.

A Chapter on Eyes.

The eyes feel a great deal worse directly after the evening lamps are lighted, and after rising in the morning. At these times they need to become used to the change of light by degrees, and it is very injurious to use them in reading, sewing or writing, or in anything which requires close attention, until they have become accustomed to the various lights of the morning and the evening. Then warm water—quite warm water—is very much better for them than cold water. Never use anything else if you can help yourself, and when your eyes feel strained and overworked, take a cup of very hot water, and apply it with a handkerchief or a sponge, and see for yourself how soothing and beneficial are its effects. It is very essential also to use the weakest or highest numbered glasses when distinct vision, at a little distance, first begins to fail.

Dr. Williams, in his valuable little book entitled "Diseases of the Eye," says that when the symptoms of loss of adaptive power begin to be felt, the eyes should be aided by convex glasses of sufficient power to compensate for the deficiency; otherwise they are fatigued by futile efforts, and yet more serious disability may result. It is useless to postpone glasses in the hope that the necessity for resorting to them may be overcome. But many persons make a great mistake in procuring glasses of too strong a magnifying tendency, and thus accustom their eyes to it, and when they fall still more, as old age advances, are forced to adopt those of still greater powers. By doing this they weaken their vision too much, while they should do all in their power to strengthen it. As soon as a blur comes before the eyes, or they begin to ache or feel badly, put the sewing, book or pen directly down, and rest the eyes for at least fifteen minutes or half an hour. This is an imperative duty if you desire to keep your eyesight, and it is almost, if not quite, as important to you as your tongue, and much more so than your ears.

The sight in thousands of eyes has been sacrificed by over work, for the power of sight is easily injured when the physical system is prostrated by illness, and many mothers have done their eyes serious injury by endeavoring to read, write or sew when recovering from confinement. They know that many articles need attending to in the family clothing, and with weak heads and eyes, they undertake to do a little mending, which may prove disastrous to them. We delight in well-mended apparel, but do let me beg of you, mothers, not to try your eyes with darning stockings, shirts, etc., while you are still prostrated on a bed or couch, or kept a prisoner in a rocking chair.

Reading while lying down will always weary and injure the eyes, and is frequently a very serious cause of weak eyes.

Near-sightedness is common among young children, and many parents are unwilling that they should wear glasses on account of their youth; yet it is a great loss to them to go on, year after year, without ever obtaining a distinct, clear view of anything which is not close before their eyes. They lose the beauty of a distant landscape, and are debared from much enjoyment, and it is far better to allow them to use glasses at ten years old, than to wait until old age comes on, before they can avail themselves of the privilege of the far-sighted.

Aching eyes are far more common than they were twenty years ago, and for the benefit of the many who suffer from them, I give a recipe which has been of the greatest service to me, and which cannot injure any one, if simply applied to the outer lids of the eyes, and allowed to penetrate:

Two ounces of camphor water, four grains of morphia, and as much powdered borax as will dissolve in the water. Apply to the eyes half a dozen times a day, by pouring a little of it into the palm of the hand, and dipping the eye into it, or by wetting a fine linen cloth and laying it over the eyes. Label the bottle "Poison," on account of the morphia.—*Country Gentleman*.

ABSORPTION OF TOBACCO.—That tobacco does lodge in the tissues is evident from the following fact. The hydropathists have among their processes one which they call the wet sheet pack. The patient is enveloped in a wet sheet, and then—over this—in blankets. By this process they claim that through the operation of the principles of endosmosis and exosmosis, the water of the sheet is made to enter the body, while at the same time impurities are withdrawn therefrom. Now let the habitual user of tobacco be subjected for an hour to this process. When at the expiration of that time, his envelopments are taken off, the odor of tobacco coming from his body, and from the sheet in which he has lain, will be as perceptible to every one present as though a cigar had just been smoked in the room.

REMEDY FOR COLD IN THE HEAD.—Inhale hartshorn through the nostrils six or eight times a minute until relief is obtained. Then after an hour or so repeat again. This remedy is used in France with good results.

A MAN WITHOUT MUSCLES.—A faro-dealer in this city, about four years ago, was compelled to relinquish his profession by a paralysis of his right fore-finger. The nerve cell (in the spinal column) which supplied the joint had died from overwork, and the muscles of the finger gradually passed away through disuse—atrophied, the doctor called it. The dead cell in the spinal marrow in some way, by contact or sympathy, destroyed its neighbor, which controlled the same finger on the left hand. The atrophy extended over both hands, up the arms to the chest, shoulders and neck. At the present time there is not a muscle in those portions of the man's body. The arms hang useless and absolutely fleshless—mere skin and bone. The intercostal muscles are gone, and the man can make no respiratory movements requiring their actions; the esophagus, trachea, and spinal column clad in skin, and that is all, the processes of the latter standing out as plainly as in a skeleton. The head unsupported, hangs down on the chest, as if it were merely tied on. By a movement of the loins the man can throw his head over so that it will fall resting on his shoulders and back, but otherwise than thus, mechanically, he cannot control its motion. What parts the disease will next attack is a question with the physicians at Bellevue, where the case was shown yesterday, but the result is hardly doubtful. Breathing is done now wholly by the diaphragm, and must cease if that be attacked.—*N. Y. Ez.*

THE "BLEEDING FAMILY."—A singular story is told by a Milbridge, Maine, physician, of Rufus Mitchell, aged 30, who recently bled to death from a slight cut: "He was one of those unfortunate men who bleed from the smallest scratch of the skin, and many times he has lain and bled till it seemed that the blood had all run out, and then would gradually recover. This time the cut was quite large and he lived but a few hours. There is something remarkable about this family, who are here termed as belonging to the bleeding family. None but the males bleed, and they are the sons of the females of the same family. For instance this man has left children; none of them will bleed, but if the girls should have boys in their families, they will be of the bleeding kind, but the boys are themselves free and their families will be the same. I cannot explain this. I have practiced in the family more than twenty years. During this time a number of them have died from this cause, and others have lived often dangerously. They seem to be as careless about edged tools as though they were like other people.

THE CROUP.—When there is indications of an immediate attack of croup, or rather when the symptoms indicate that it is already at work, grease the breast thoroughly with goose-grease, and lay on it a double thickness of flannel. If the strangling comes on suddenly, mix Scotch snuff and lard together, put on a piece of brown paper, and apply instantly to the breast, rubbing the throat meanwhile with hot grease, or lard, or oil. Or you can do this: Dip a flannel in water, as hot as it can be borne, lay it on the breast, take salt hutter, spread on a piece of brown paper, and apply to the breast and throat. Salty butter rubbed on the throat and chest, just before going to bed, is a most excellent remedy for sore throat; two or three applications being enough to effect a cure.

COFFEE.—Dr. Hahnemann, the author of homeopathy, in an essay on the effects of coffee, states that it prematurely stimulates and develops sexual passion in both sexes, and brings the human body to its full or maximum maturity ten or fifteen years sooner than we should reach this period without it, which if true is really a frightful fact; for if we hasten or force human life ten years in the first stages, we of course shorten it that much in the later stages, and this amounts to a total loss of so much human life, from the action of coffee alone upon the organism. And now add to this, the debilitating and enervating effects of tea, tobacco, spirituous and malt liquors, what must be the cum total of the losses? F. M. A.

SMALLPOX NO RESPECTOR OF PERSONS.—During the year 1872 there died of smallpox in the city of Philadelphia 2,500 persons. It was confined to two districts of the city, situated at opposite ends—the one a foul and unwholesome locality, where the sanitary regulations are never observed; the other inhabited by people in good circumstances, and the streets and dwellings of average Philadelphia cleanliness. Neither the filth of one nor the cleanliness of the other had any influence in preventing or increasing the spread of the scourge. It remains now to be discussed by medical authorities, and it is to be hoped in the interest of humanity some solution will be reached.

FRECKLES.—For the benefit of young persons afflicted with freckles, we would inform them that powdered nitre, moistened with water, applied to the face night and morning, will soon remove all traces of them.—*Druggists' Circular*.

REMEDY FOR CHILBLAINS.—A writer in a Vienna medical magazine says that a concentrated solution of chloride of iron is an unfailing remedy for chilblains.

MINING SCIENTIFIC PRESS

B. EWER..... SENIOR EDITOR
DEWEY & CO., Publishers.
A. T. DEWEY, GEO. H. STONG,
W. R. EWER, JNO. L. BOONE.

Office, No. 338 Montgomery St., S. E. Corner of California St., diagonally across from Welle, Fargo & Co.'s.

Subscriptions payable in advance.—For one year, \$4; six months, \$2.50; three months, \$1.25. Clubs of ten names or more, \$3 each per annum. \$5, in advance, will pay for 1½ year. Remittances by registered letters or P. O. orders at our risk.

Advertising Rates.—1 week. 1 month. 3 months. 1 year.
Per line..... 25 .80 \$2.00 \$5.00
One-half inch..... \$1.00 \$3.00 7.50 24.00
One inch..... 2.00 5.00 14.00 40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper, inserted at special rates.

San Francisco:
Saturday Morning, March 15, 1873.

Legal Tender Rates.—S. F., Thurs., Mar. 13.—buying 87½; selling 88½.

Table of Contents.

GENERAL EDITORIALS.—Foundry Notes Mining Commissioner's Report, 161. Past and Present of our Mines, 163. Gold Sands: Speculum Analysis, 169. **ILLUSTRATIONS.**—Fulverizing Barrel, 161. Pratt's Steam Pump; An Improved Fence; Withington's Patent Wheel, 169. **CORRESPONDENCE.**—Rush Valley Mining District, Utah; Effect of Frost on Iron; Robinson District, Nevada; What's the Matter, 162. Pan Amalgamation, 168.

MECHANICAL PROGRESS.—The Band Saw and Band Sawing; Conveying Air Through Pipes; A Three Cylinder Engine; The Inventor of the Circular Saw; American vs. English Engineering, 163.

SCIENTIFIC PROGRESS.—The Road to Scientific Success; Scientific Predictions; Darwin and Agassiz; A Flame Organ; Blue Sky and Water; Iron in Salt Water; Coal Oil Fuel in Russia, 163.

USEFUL INFORMATION.—Relative Weights of the Sexes; Danger from Matches Diminished; Zonipsa; Petroleum for Boats; Tea in India; A Sandpapering Machine; Absence of Fear in Wild Animals; The Sexes; Eggs in Case of Trouble; Street Making in London, 167.

GOOD HEALTH.—A Chapter on Eyes; Absorption of Tobacco; A Man Without Muscles; The "Bleeding Family," 167.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 164.

MINING SUMMARY from various counties in California, Nevada, Idaho, Montana, Utah and Arizona, 165.

MISCELLANEOUS.—Nitrate of Soda; Railways in South America; Singular Discovery of Gold; Assaying Lead Ores; Anti-Sea-Sick Cabins, 166. Patents and Inventions, 169. The Mother Lode of California; Patents in Japan; Little Cottonwood Mines and Railroad; Product of the Nevada Mines, 170.

PROF. WM. P. BLAKE AT VIENNA.—We are pleased to learn that the United States commission of the Vienna Exposition, have decided to send Prof. Wm. P. Blake to Europe for the express purpose of studying up the Vienna Exposition, and reporting upon it for the special information of the citizens of this country. It is probably known to most of our readers that the Professor, who was sent to the Paris Exposition as a representative of this State, was retained by the Government at Washington, after his return, to edit the reports of the various State and National Commissioners sent out from the United States to that Exposition. The able and satisfactory manner in which he performed that responsible and delicate task is sufficient guarantee that rich lessons of experience and profit will be harvested in the new field to which he is now accredited.

Mr. Blake's well-known knowledge of, and interest in, the mines of the Pacific Coast will insure for that department of his work much valuable information which will be of special interest to Californians. The readers of the Press will probably hear from the Professor, during his stay at Vienna.

WASHOE BULLION SHIPMENT.—During the month of February there was shipped through the office of Welle, Fargo & Co., in Virginia City, \$1,629,993.16. This was at the rate of \$53,214.04 per day, or \$19,559,917.92 per year, reckoning from February's production, which is the shortest month in the year.

DR. CARR still continues his industrial lectures to the laboring classes of Oakland, and we understand that the attendance is increasing, which shows the degree of interest people will take in such subjects when they are explained to them, divested of technical details and abstruse language.

AUSTRALIAN MAILS.—Webb's line of steamers, running from this city to the Australian colonies having been withdrawn, all correspondence in that direction must go by the British mail via England.

The Past and Present Values of Our Mines.

On looking over the prices of mining shares as they are quoted to-day, a person who was not fully initiated in the mysteries of stock gambling might suppose that our great gold and silver-bearing ledges were exhausted and that the quartz mines which have been the great source of the wealth and prosperity of California, Nevada and Idaho, were things of the past, and no longer presented any chances for a safe investment of capital. We acknowledge, that it is impossible to conceal, and very difficult to explain away the fact, that, within the last ten months, the mines on the Comstock alone have depreciated in value to the extent of eighty millions of dollars, and those of every other mining district on the Coast in like proportion. It is equally difficult to explain how this great depreciation has taken place in the face of a steadily increasing yield of bullion, and no increase of expenses worth mentioning. The quantity and quality of the ore extracted throughout California and Nevada have been fully up to the standard of any preceding years, and yet in place of dividends, with some half dozen notable exceptions, we see nearly every mine in these two States and in Idaho, levying frequent assessments. In Virginia alone about four thousand tons of ore are sent daily to the various mills of that locality, every ton of which leaves a fair margin for profit; notwithstanding all this, there are but two mines in that section, that have ever paid a dividend for years. These are the Crown Point and Belcher, and even in these two instances, the dividends are very irregular, being frequently passed for three or four months at a time, when there is about half a million dollars lying idle in the treasuries of each of them. Out of some thirty-five or forty California mines, which are daily gambled in, in the San Francisco Stock Board, no one ever expects to hear of a dividend from any one of them, except the Amedor and Eureka. In Ely district there are about fifty incorporated companies, yet the Raymond & Ely is the only mine paying a dollar to the shareholders, in Belmont there are none. In White Pine, none; and from Eureka, which is probably the most shamefully swindled district of all, there has been no dividend from any of its mines for the last fifteen months. In Idaho, the management of all the Owyhee mines has been notoriously corrupt, that no one expects ever to receive a dollar from that section of country, unless as in the case of the Mahogany last year, a dividend were to be declared, in order that a heavy assessment might be levied the following week.

All these things are working sadly against the mining interest of the country both at home and abroad. In England with their staid, old country notions of honesty and fair dealing, they insist that our mines are failures, from the fact that they are non-dividend paying, and require to be kept up at such an enormous outlay of money. They argue that as the Trustees of every company are elected by the majority of the shareholders, that these men are probably the largest owners themselves, and certainly must have the interest and welfare of the mines at heart. They little know that in this country men are often elected Trustees who do not own a single share of stock, or who have merely hired it for election dry, in order that they might have a fair chance to plunder a mine for twelve months; let our English cousins console themselves with the reflection, that they receive dividends from many of their mines in this country, which, were they controlled by San Francisco stock sharps, would be a heavy drain on the pockets of the shareholders.

However, this gigantic evil is working its own cure. No outsider now wants to touch mining stock at any price, but let it go for assessment or any thing it will fetch, nor is it likely that there will be any change in this state of things, until the present ring of mining trustees withdraw and give place to men who have the confidence of the community.

VIRGINIA CITY has at last got the epizootic and the livery stables, etc., are all closed while it is in progress. Ox teams are in great demand for hauling quartz, since local transportation by ordinary means is out of the question. The scarcity of wood having been partially overcome they now have another annoyance in the shape of scarcity of horses.

THE MARIPOSA Mill at Virginia has been compelled to shut down for want of fuel.

Pan Amalgamation Again.

[Written for the MINING AND SCIENTIFIC PRESS.]

The following interesting communication explains itself:

In your issue of March 1st I notice a summary of the lecture lately delivered by Mr. Riote on the subject of Amalgamation. The lecturer, as quoted by you, decried the use of chemicals in pans, under any and all circumstances, declaring that their action is always detrimental and never beneficial. Further on, however, he admits the advantage of using certain chemicals in working slimes, but makes the remarkable assertion that their action in this case is purely a mechanical one. Now these sweeping denunciations of Mr. Riote being directly opposed to demonstrated facts, and merely the echo of popular prejudices, they cannot be permitted to go unchallenged.

The opposition to the use of all

Chemicals in Pan Amalgamation

Is mainly due to the indiscriminate use made in early days by ignorant persons of chemical re-agents, which had nothing to recommend them but a high sounding name or a brilliant color; but I propose to show that, by employing the proper substances, in adequate quantities, the most favorable results have been obtained, dispensing in many instances with the necessity of roasting the ore, rendering possible the profitable reduction of minerals which otherwise could not have been touched, and giving rise in Virginia City and environs to a great and entirely new branch of industry. All this has been effected by the use, in reasonable quantities, of sulphate of copper and salt, which, by their mutual decomposition, form chloride of copper. The beneficial

Action of these Substances

On silver ores has been known since the middle of the 16th century, existing in Mexico the Patio process, which to this day has never been abandoned or materially altered. It is needless to go into the chemistry of the process, which has been often and variously discussed. It is sufficient to show by a similarity of result that the reactions are essentially the same as when sulphate of copper and salt are used in the pan, with several advantages in the latter method, namely: a high temperature, violent motion, and the presence of a large amount of iron. These all compensate for the apparently very short time allotted to the chemical reactions in the pan, and the iron, moreover, produces a galvanic action which diminishes the chemical loss of quicksilver.

It has been proven in Mexico that merely by increasing the number of "repases" the time necessary to the amalgamation of the ore could be reduced from twenty-five days down to three days. The "repaso" consists in causing horses or mules to walk backwards and forwards through the slushy mass of pulp. If we consider how imperfect is the trituration of ore and quicksilver, and how feeble the motion effected by this means, there is no cause for surprise that the amalgamation should be reduced to a period of six or seven hours by the great heat, violent motion and galvanic action in pan amalgamation.

Bluestone and Salt

Were used by Washoe millmen in early days, but never in an intelligent manner—some using either salt or bluestone separately; others the two together, but always in infinitesimal quantities. It is now four years since those chemicals were first used in pane on a large scale. Up to that time most of the battery slimes, especially from the low-grade ores, were allowed to run to waste in the Washoe mills, as only 35 per cent. of their value could be extracted by the ordinary system of amalgamation. Experiments made at the time referred to proved that by adding to the elimes after their introduction into the pan, a quantity of sulphate of copper and salt, which, to the then prevalent notions, appeared enormous, over 75 per cent. could be extracted. From that time on no more slimes were allowed to run to waste. Mills were built for the especial purpose of reducing them by the new process, and have paid their owners enormous profits. It was soon discovered that the "process" was equally well adapted to the

Working of Tailings.

It became possible to work tailings assaying only seven or eight dollars per ton, and hundreds of tons are now daily reduced in Dayton, on the Carson river and elsewhere, which would yield but the merest fraction of their precious contents under the old system of amalgamation with quicksilver alone. The enormous demand for sulphate of copper caused the erection of a

Bluestone Factory

By Birdsall & Co., in Dayton. They manufacture on an average 4,000 pounds of bluestone daily, which is barely sufficient to supply that one district. No candid mind can suppose that this industry could be kept up were its

products not indispensable to its patrons. But the

Advantages of these Chemicals

Are not restricted to Virginia ores. They have been most successfully employed in the Mill of the Meadow Valley Company from the very start, and ore which with quicksilver alone would barely yield forty-five (45) per cent. of its value, here by their additions been made to yield seventy-five per cent. and over. This was well demonstrated at one time, when the supply of bluestone became exhausted. The yield fell off one-half, and only that portion of the silver was extracted which, as showed by numerous chlorination tests, was naturally present as chloride of silver. Neither salt, nor sulphuric acid and selt, nor any other chemicals stand were found to have any effect in increasing the yield; and not until the receipt of a fresh supply of bluestone did the ore give its former satisfactory yield. Various experiments have proven that the sulphate of copper and salt are indispensable in working these ores, increasing the yield by 35 to 40 per cent., except on certain lots of ore, where the greater part of the silver is naturally present as a chloride. The Raymond & Ely Company also has recourse to the use of these chemicals when their ore, usually very "free," becomes more refractory. The same process has been introduced into several other mining districts; in one instance by Mr. Kustel, from whose book, printed ten years since, Mr. Riote quotes a garbled extract. In this instance Mr. Kustel found the yield increased 40 per cent. The quantity of bluestone necessary to produce these results is in reality very small, rarely exceeding ten pounds per ton of ore, and in the case of low-grade tailings falling as low as five pounds per ton. The quantity of salt used is from two to three times the weight of the bluestone.

Exceptional Cases.

Not in all cases can these chemicals be used with equal advantage. Certain combinations, such as ruby silver, or ores containing appreciable quantities of galena or zincblende, etc., must be roasted. The presence of carbonate of lime, or any alkali tends to decompose the chloride of copper and destroy its effect, or when the silver appears naturally as a chloride the addition of chemicals is to a great extent superfluous, but it may safely be stated as a general rule that wherever ores are amalgamated raw, the addition of bluestone and salt will always prove beneficial, and never detrimental.

In regard to the pernicious

Action of Chloride of Copper

On quicksilver, it is safe to say that it is more apparent than real, on a large scale. The tilling mill around Virginia City suffer little more loss than the ordinary quartz mill, which use no chemicals; and in other districts where chemicals are used, the ores carry large amounts of lead and other base metals, which of themselves occasion a loss of quicksilver, which it would be unjust to attribute to the action of the copper salt. The

Loss in Working Slimes

Is abnormal and mechanical, the clay acting upon the particles of quicksilver in the same manner as grease, causing them to float and be carried off with the residues. This is merely a matter of dollars and cents, and while a supply of quicksilver can be readily obtained, millmen are not likely to consider the matter from a politico-economical standpoint. This argument also holds good in the matter of depreciated fineness of bullion, since bullion is made for sale and not for show; the discount suffered on base bullion stands in no proportion to the extra amount of silver extracted from the ores by the use of chemicals. In view of these facts, it is to be regretted that Mr. Riote should have publicly and in the name of science constituted himself the champion of exploded theories.

That the sphere of usefulness of sulphate of copper and salt can be greatly extended, admits of no doubt. The yield of Comstock ores would be greatly increased thereby, and hundreds of thousands of dollars which are now lost or only partially recovered at the expense of a second working, would go to swell the profits of stockholders. ALEXIS JANIN.
San Francisco, March 12.

FORMATION OF MOUNTAINS AND VALLEYS.—We

notice that the Loudon Mining Journal calls the attention of its readers to the fact that Mr. J. S. Phillips, in his California hook—"The Explorer's, Miner's and Metallurgist's Companion," set forth therein what is now known as Mallett's theory of the formation of mountains and valleys, some two years in advance of its promulgation by Mr. Mallett. Our readers will recollect that we made an extended reference some weeks since in these columns to the priority of claim on the part of Mr. Phillips.

The Mining Journal also contains the following paragraph as a statement of recent ideas, with regard to earthquakes which he entertains, and which he has embodied in the form of a foot note for his second edition. "As the earth continued its cooling, other internal, hollow globes, would in like manner be forming from plastic to solid states, which, when compressing laterally, as described in the crumpling of surface mountains, certain portions would then rub violently against the interior of the colder outer shell, and produce such motions as earthquakes, a greater degree of heat and force for the pent up gaseous elements to release themselves through surface volcanoes."

Gold and Iron Sands.

Recent developments, here and in New Zealand, are directing public attention once more to the auriferous sands of our northern Coast. The presence of gold in these sands in paying quantities is well understood; and it is also known that immense deposits of these sands exist high above the present sea level, known as ancient beaches formed prior to the latest upheaval. For twenty years or more these sands have been worked by a few men, sometimes with great profit, by the ordinary mode of sluicing and amalgamation with copper plates.

In this way fully three-fourths of the gold is lost, owing to the gold being in fine, flaky particles and the black sand very heavy. Recently one of the heaviest operators in these sands, F. G. Lockhart, who has a valuable claim on the ancient ocean beach near Coos Bay, has successfully tried the chlorination process. From several tons worked, it is stated he obtained an average of \$29 per ton at an expense of \$4 per ton, and saving over ninety-five per cent.

This result being eminently satisfactory it is likely to give a new impetus to

Beach Mining.

The absence of sulphurets from these sands, so simplifies the process that its advantages are at once apparent to experienced miners. To mine without blasting or crushing rock; without sinking or pumping out shafts; without the use of costly machinery, quicksilver or gunpowder; and without constructing long water ditches or flumes; in short to mine extensively with a small capital and at little risk, are inducements which are not likely to be overlooked by practical men.

A New Value in the Sands.

But the gold in these sands gives them but a quarter of their actual value. The magnetic black sand, or titaniferous iron-sand, as it is usually called, contains, when pure, 72 per cent. of iron, and by the proper mode of smelting, is convertible directly into excellent steel, almost as cheaply as pig-iron is produced. This is now being done in New Zealand where similar sands exist in abundance. The latest Auckland papers give full accounts of the successful smelting of these iron sands, resulting in the production of superior qualities of both iron and steel, at a cost not exceeding \$25 per ton. At the present prices of iron and steel this affords a pretty big margin for profit, and as a consequence some excitement prevails there and companies are forming to enter largely into the business.

The same thing may be done here undoubtedly; and it is high time our capitalists commenced the development of our vast iron resources. The present time is favorable for doing so, with a guarantee against loss in the undertaking. The gold in the iron-sand of Gold Bluff and other points on our Coast, will pay all expenses of establishing smelting works for iron and steel and leave a profit besides. Five, or at most ten thousand dollars, is ample capital for erecting chlorination works at the mine, and the profits of these works will in a few months build smelting works for the manufacture of iron and steel on a large scale. Fuel and water are abundant, and navigable waters connect the localities of the mine with this city.

Should it require some experimental trials to learn the process of

Smelting this Sand,

It need be no discouragement, since the gold obtained by chlorination will meet all expense. It is well-known that steel is simply carbonized iron. Pig-iron contains too much carbon, and, ordinarily, it contains sulphur, manganese, and other impurities, which have to be eliminated before it can be converted into steel by the orthodox process of manufacture.

Wrought iron is that metal in its purest form. If we have one that is free from impurities the melted product is necessarily free also from them, and therefore pure iron. Then, by combining with it the proper proportion of carbon, during the process of smelting, the result will be steel. The iron obtained by smelting this sand in New Zealand is malleable, like wrought iron, and consequently must be quite pure. A portion of the product turned out thus far in their operations is iron of this character, and the remainder is steel of superior quality. This of course is the portion that is efficiently carbonized by the fuel used in the operation of smelting. Experience will soon

teach them how to convert the whole into steel before it leaves the furnace.

The question as to what are

The Proper Fluxes to Use,

And the proportion of each to be used, in smelting these iron sands, must be solved in the same manner by experience. But it cannot be a difficult problem for experienced smelters to solve. Clay and lime used together in proper quantities, are the proper fluxes for silicious ores like these sands. There is sufficient silica in the form of common sand mixed with these iron-sands of our beaches, to reduce their average value probably to 50 per cent. of iron. In New Zealand the beach sand is mixed with clay and lime and made into bricks, which are sun-dried and then broken into lumps and smelted in a blast or cupola furnace. It would clog the blast if fed into the furnace in the form of sand. Other forms of furnace might be used probably and the labor of making the bricks avoided. Perhaps the new oxy-hydrogen heat, resulting from the combination of superheated steam and hydro-carbon oils, will prove better adapted to this branch of the smelting business than the fuel heretofore used. Shall we let the New Zealand people get far ahead of us in this new enterprise?

An Economical Fence.

The accompanying cut shows a patented method of constructing fences which is extremely simple. It is stated that three men can put up 600 yards of this fence in a day. In mountain districts, where small fences are required, and wood has to be hauled any distance, a wood and wire fence of this description will be serviceable, being strong and light.

In building this fence, the first thing to be

AN IMPROVED FENCE.

done is to set the posts firmly in the ground, placing them from twenty to thirty feet apart. Two wires are drawn through a hole in the first post set, and through similar holes in other posts to any convenient distance. The wires being fastened at the first post, are left slack along the line for the insertion of pickets, and wound around the last post of the section of fence under construction, to keep them from being drawn back during the insertion of the pickets. The slack being taken up, the battens of the palings are successively set in a shallow trench, dug between the posts on the fence line. The tops being inclined until they will enter between the wires from the under side, are then brought into a vertical position. As fast as the palings are inserted their butts are held by filling in and packing the earth in the trench. The wires may be tightened, if they should ever become slack, by simply putting a twist in them—using a pair of palings for this purpose, and turning them in opposite directions. This fence is impassable to large or small animals, and no openings can be made by pulling off pickets. The pickets take the strain off the posts, each one, in fact, being a post.

The wire usually used in building this fence is No. 10 galvanized, such as is used for telegraphic purposes; 100 ft. weighs five pounds, and costs in this city 60 cents, which is 20 cents for each rod of fence. Split or sawed palings can be used, and, when necessary, willows or small bushes, which will of course lessen the cost. Wiester & Co., No. 17 New Montgomery street, are agents for this Coast, and can give further information to those desiring it.

THE DIFFERENCE. — An English paper comments on the similarity between California and Australia in several particulars, especially the agricultural, wool and mining interests. Interest on money in Australia is three per cent. per annum, while here it is from 10 to 15 per cent. per annum. The *Call* thinks the difference is simply because California is full of enterprise, while Australia is lacking in this element of prosperity.

The Prall Steam Pump.

While at the Pacific Foundry this week we had an opportunity of examining a steam pump, which for simplicity of construction and operation excels anything we have before seen. It is simply two cylinders joined together above and below with pipes, and is constructed without pistons, piston rods or stuffing boxes, levers, cams, cranks or fly wheels. There are no moving parts other than the valves, and it is noiseless in operation, as the water flows quietly in and out of the cylinders, forced by the steam. The steam exerts a direct pressure in forcing water out of the pump and by creating a vacuum, through its condensation, utilizes the pressure of the atmosphere to lift the water into the pump.

As we will shortly give an illustration of this remarkable invention, we will not go into detail of construction and operation at present. It will sound strange to say that it is frictionless and requires no lubrication, nevertheless such is the fact. By placing this pump 30 feet above the supply, water can be elevated and flowed into a tank on a level with this pump, with a pressure of steam of from one to two pounds, and for forcing water every foot of elevation above this point only half a pound additional pressure is required. The one we saw in operation was run by a small portable boiler and the steam it threw was perfectly regular, showing no intermittent action. It requires no engineer to run it and is not liable to get out of repair. It is worth the while of parties who use steam pumps and have the opportunity, to examine this one and see it in operation.

A New Iron Wheel.

The accompanying cut shows a wheel of improved construction, which is particularly applicable to wheelbarrow and truck-wheels, and the wheels of toy-wagons. Its construction is quite simple, and consequently cheap, while the peculiar method of making it will render it strong and durable. The tire is made

WITHINGTON'S PATENT WHEEL.

of iron or other metallic substance. The spokes consist each of a metallic bar or rod, which is bent as shown, so that each half will serve as a bracing spoke. The bend of the rod is flattened, so as to fit against the inner face of the tire, and a rivet, screw or other fastening device, is employed to secure it in place against the tire.

The opposite end of these spokes or rods, which is next to the hub or axle, is provided with screw-threads, upon which a nut is screwed, and the end of the spoke enters a hole in the hub or axle, directly under the nut. By screwing this nut up or down on the spoke the spokes can be tightened or loosened as desired, the nut being against the hub. By this means a strong, substantial wheel is constructed, which can be made very cheaply. For agricultural implement wheels it is particularly applicable. The device has been patented through the agency connected with this office, by George Withington, of Ione City, Amador Co., Cal.

NORTHERN PACIFIC RAILROAD.—The following named gentlemen were elected Directors of the Northern Pacific Railroad, at the annual meeting of the company, held in New York on the 12th inst. W. G. Fargo, Geo. W. Casa, R. D. Rice, Charles B. Wright, W. B. Ogden, Frederick Billings, J. G. Smith, W. G. Moorhead, A. G. Barney, William Windom, James Stinson, B. P. Cheney and Albert A. Catlin. It is understood that within a few weeks the Yellowstone, Lake Penn d'Oreille and Puget Sound sections of this line will all be in process of construction.

THE RAYMOND AND ELY SUIT.—A dispatch from Pioche states that the case of the Raymond & Ely vs. the Kentucky has been continued until March 17th. Several prominent lawyers have arrived there from San Francisco and Virginia City to argue in the great mining suits now pending in the District Court.

Spectrum Analysis.

Professor Neri's second lecture on Spectroscopic Analysis, delivered on Thursday evening of last week, was still more largely attended than his previous one, a fact which shows that this community is not at all behind our sister cities at the East in its appreciation of science.

The first lecture having been more particularly devoted to the history of the discovery of the spectroscopic and its wide and wonderful appliances; the second aimed to show how and by what means that instrument has been able to accomplish the astonishing and important results which have been derived from it. This is done by the power which it possesses to

Analyze Light.

It is by the light given off by the various substances—and by light alone—that the spectroscopic is able to determine the character of the substances to which it is applied. We know that light possesses certain properties, and that the light of different substances varies in its nature. The spectroscopic does not tell us in what the nature of the difference between the light given off by various substances consists; it simply shows that every substance known, when heated to a point of illumination, presents certain phenomena in passing through the spectroscopic, which is peculiar to that substance, and which is possessed by no other substances. Hence there is never any danger of mistaking one thing for another, when submitted to the test of that instrument.

Various interesting and instructive experiments were shown to prove those positions, during which the magnesium light, the oxy-hydrogen light and the electric light were shown—each having its peculiarities. The latter approaches nearer to the light of the sun than any other illuminating medium known. The electric light possessed an intensity of about 600 candles, or one-quarter that of a sunbeam.

What is Light?

What is the substance of light, what its essence, its nature? Of this nothing really certain is known. The early idea of the nature of light—and that which was supported by Newton—was that it consisted of an infinite number of minute particles or molecules, which were projected upon the retina of the eye, thus conveying to our senses the idea of light and color. This was called the corpuscular theory, but is now abandoned.

The Modern Theory

Is that light is due to the vibrating molecules of luminous bodies. Their vibrations, when they emanate from a sun or star, are communicated to and set in undulatory motion a very thin elastic medium, which pervades all space, and by which motion each light is conveyed to our vision—not that the particles of the medium travel, but that the motion is transmitted, just as the waves of the sea move forward, while the water itself is at rest or perhaps moves in an opposite direction. Different kinds of light move with different degrees of motion with waves of different size or different velocity.

Reflection and Refraction of Light.

Unobstructed light travels in straight lines; but when it meets any substance which it cannot penetrate it is thrown off at a greater or less angle. Several pleasing and instructive experiments were introduced by the use of mirrors, etc., to show and explain this principle.

Some substances, however, although they do not reflect and turn entirely aside the rays of light, hinder them, more or less in their passage. Some things like the prism cause the rays of the sun to diverge more or less from a direct line, and also to separate into different colors. It also shows that certain rays convey no heat, or but little, while others convey a large amount of heat—the latter are colorless.

Various interesting experiments were shown with prisms of different substances. The light was made to pass through a small globe filled with water, which projected an arch of colored light upon the screen—a rainbow in fact.

Another and perhaps the most interesting exhibition of the evening was the showing by means of Colladon's Fountain, that light thrown horizontally into a vessel of water will be so entangled or mixed with it as to follow the course of that of water when drawn off in a curved stream into another vessel at a lower altitude. We have not the space to do anything like justice to this interesting and really scientific lecture.

FREIGHT.—The Central Pacific Railroad carried East during January 3,749,300 pounds of freight, among which was 19,345 pounds of base metal and 39,969 pounds of quicksilver.

The Mother Lode of California.

We have received the advance sheets of "Statistics of Mines and Mining in the States and Territories west of the Rocky Mountains," by Rossiter W. Raymond, United States Mining Commissioner, being his report for the year ending December, 1871. We make the following extract from the chapter on California, which was written by W. A. Skidmore:

The mother lode of California is a vein, or, more properly, a series of veins of quartz which has been traced on a longitudinal line, with occasional interruptions, for a length of about seventy-five miles, from Bear Valley, Mariposa County, to Amador City, Amador County. Throughout the entire distance it has a general northwest and southeast course, and an almost uniform dip to the northeast of eighty degrees.

Whether this singular formation is a "lode" or a mere accidental occurrence of a series of veins on a longitudinal line in the same belt of slates, is a question on which eminent mining engineers have differed. It has been discussed in the report of J. Ross Browne of 1868, and in my report of 1869. Mr. Skidmore considers it as a defined lode, believing that recent developments, at various points, have a tendency to confirm this theory.

The most southerly well-defined outcrop of this remarkable vein is at the Pine Tree and Josephine mines, on the Mariposa estate, at an elevation of about 2,500 feet above sea-level. From this point it takes a northwest direction, striking across the numerous spurs of the Sierras which form the divides between the Tuolumne, Stanislaus, and Mokelumne rivers and their tributaries, and terminates in the foothills of Amador County, the most northerly deep-developed claims being the original Amador and Keystone at Amador City, although many locations between these mines and the Cosumnes River are supposed to be on the same lode. Beyond the Cosumnes the lode is not traceable.

Between its southern and northern extremities it is frequently broken up and lost, (invariably so at the intersection of the principal rivers,) making its appearance again at a distance of several miles, frequently in the form of a solid wall of quartz on the summits of isolated hills on the line of its strike, these croppings being visible for many miles. The most prominent of these hills are Pinon Blanco, Quartz Mountain, Whisky Hill, and Carson Hill. At these points the lode has widened with the "blossom" of the mountain, and presents the appearance of a system of parallel veins separated on the surface, and to an indefinite depth, by "horse" matter, composed of nearly equal parts of slate, and broken quartz. Locations have been made in the majority of such instances on the croppings, parallel to each other, one on the hanging wall and another on the foot-wall of the lode, these walls being sometimes separated, as at Quartz Mountain, Tuolumne County, by a distance of from 200 to 250 feet; but recent deep developments at various points would seem to indicate a tendency of these walls to narrow, which at depths of from 1,000 to 1,200 feet, and in some cases less, would shut out the "horse" and develop a permanent fissure of from fourteen to eighteen feet in width.

The principal points at which mining has been prosecuted on the Mother lode, are Bear Valley, Princeton, and Mariposa, in Mariposa County; Quartz Mountain and vicinity, near Jamestown, Tuolumne County; Rawhide and Tintletown, in same county; Carson Hill, Angel's Camp, and Paloma, in Calaveras County; and Jackson, Sutter Creek, and Amador City, in Amador County; the deepest development having been made at Sutter Creek, where, at the Amador mine, a shaft has been sunk, and levels opened to the depth of 1,300 feet.

The entire length of locations made on the Mother lode is estimated at 180,000 feet, equal to half the distance between its northern and southern extremity. Many of these locations, however, run parallel to each other, and the ground continuously located would not exceed 100,000 feet, while the ground now in process of development (including only those claims on which work has been done in 1871) will not exceed 40,000 feet, exclusive of the Mariposa estate, on which operations are temporarily suspended owing to financial difficulties and litigation.

The longest break in the lode is between Angel's and Jackson, a distance of twenty-three miles, on which only one mine, the Paloma, near the south bank of the Mokelumne River, is generally acknowledged to be on the lode, though recent discoveries tend to prove the continuity of the lode between these points. At various points the lode "dives" for several miles, and at one point, between Whisky Hill and the Rawhide mine, it is covered by the lava flow which constitutes Table Mountain.

Throughout the entire course of the lode we find many instances of failure, manifested by abandoned works and idle mills, but these are to be attributed either to mismanagement or to the injudicious location of works at points where no pay-chimney exist. The early locations were made at any point where croppings appeared, and deep shafts were sunk, and mills erected on barren ground, without any effort to find the chimney of the vein. In this way thousands of dollars have been uselessly squandered by men utterly ignorant of mining, and these monuments of their folly have discouraged those who otherwise would have invested in quartz mining. Another cause for the stagnation of mining on this lode is the

improvident manner in which work has been carried on, resulting in the exhaustion of the surface deposits, which were worked by open cuts at various places down to the water-line, when operations ceased until shafts could be sunk and hoisting-works and pumping-machinery erected, the owners of the ground having committed the common error of failing to keep their ground developed in advance of their milling capacity. Perhaps a third reason may be found in the superior attractiveness of the mines of the neighboring State of Nevada, where fortunes are made (and lost) with greater rapidity in mining operations.

Patents in Japan.

Japan is very rapidly taking her place among the progressive nations. Steam power, telegraphs, railways and modern appliances are everywhere being introduced in that country and in May last the following patent law was created. Like the patent law of Mexico it is a little behind the age, as its privileges appear to be restricted to persons resident in Japan.

The Patent Laws of Japan.

Henceforward exclusive permission to trade in newly invented articles of all kinds whatever will be granted to the inventors; in consequence whereof, should any person residing in any part of the country be desirous of obtaining such exclusive permission, the application shall for the present be made to the Home office in accordance with the regulations which follow.

Patents shall be granted for a term of years to all persons who increase the convenience of life, who newly invent any chemical apparatus, machinery, utensils, or furniture, weapons, woven fabrics, etc., or who improve existing furniture or utensils. The term of years shall be fifteen years, ten years, or seven years, according to the value of the invention.

Any person desirous of obtaining a patent shall send in his application to the local authorities of the district in which he resides, accompanied by a description, drawings, etc., which shall be forwarded to the Home office, and the Home office shall issue the patent.

The objects of the invention or the improvement shall be carefully drawn in cross section and plan, and in the case of machinery the parts must be numbered or lettered in accordance with the description, so that everything may be clearly comprehensive at a single glance; and the seals of the inventor and of his surety must be attached to the drawings. Models may be furnished of articles of which drawings can not easily be made.

When the document containing the patent is issued by the Home office the local authorities shall deliver it after having obtained a receipt from the inventor and his surety.

A duty of five ryo (\$5.30) shall be paid annually in advance during the period for which the patent is granted into the hands of the local authorities. The duty may be increased or diminished according to the nature of the invention. The amount shall be forwarded to the Home Department as soon as it is collected. No duty shall be paid until six months have elapsed from the granting of the patent, that period being allowed for the inventor to try whether the sale be remunerative, and when he has ascertained that it is remunerative he will pay in one year's duty to the local authorities.

If from the trial made during the first six months the sale turns out to be unremunerative the application may be withdrawn at the option of the patentee, but in case such application be made after the expiration of the six months, the duty for one year already paid in advance will not be returned. The application sent into the Home office will receive consideration according to priority of arrival.

Where the invention of another has already been improved, the application must distinctly state the name of the original inventor and the nature of the improvement. Where the invention in respect of which an application is made resembles a prior invention by another individual, but actually differs in construction or use, the points of difference must be clearly laid down in the application.

No patent will be granted for articles of general convenience, though the inventor be known beyond the possibility of mistake, and be yet alive, if the invention has been in general use for several years previous to the application.

Separate patents will not be given to each individual who may have combined with others to produce an invention, but a single patent will be issued in the name of all the partners of the company.

The owner of a patent may freely dispose of it for such sum as seems fit, during the period for which it has been granted; and both parties shall make application to have the fact endorsed upon the patent. The patentee is at liberty to establish branch shops in his own name, or to teach others how to make the articles patented by him. Should the patentee die before the patent expires, he may leave the patent to a relation, but application must be made to have the transfer endorsed thereon.

The Home office shall publicly notify in each case that a patent has been granted to such and such a person, of such and such a place, giving also the names of the department, prov-

ince and the seat of the local authority, in consequence of his having invented such and such an article. Should the patentee incur such losses during the term of years as he is unable to make good, if the article after due inquiry is found to be of indispensable public necessity, an extension may be granted. Each separate article must bear the words "by Government sanction," together with the name of the inventor. Fines shall be imposed on persons who fraudulently make use of a patentee's name, or who, not being in the enjoyment of a patent, make use of the term "by Government sanction."

Little Cottonwood Mines and Railroad.

A correspondent of the *Alta* writes as follows from Little Cottonwood: In my first communication of the 4th instant, I promised further information in regard to the Little Cottonwood railroad, which is now under way between Sandy and Granite. The grading of this road was first started in 1871, by the Utah Southern, they then intending to complete this branch to Granite during that year; in fact, the track was laid about a third of the distance and the grading done nearly half way; but, as all the ties and rails were needed in extending the main road further south, the track was taken up and sent thither, and the work ceased for a time. As the ore so rapidly accumulated at the mines, and no other means of disposing of it but by teams, it was necessary that some other way be provided, by which regular shipments could be made, consequently, last fall Mr. Sharp, Mr. Jennings, Warren Hussey and others formed a company and immediately proceeded to work. The grading between Sandy and Granite is now nearly finished, and ties and rails are being laid as fast as they can be procured.

This company evidently intend to have the cars running to Granite before commencing the ascent of the cañon, which is a work that will require a vast amount of labor and no small amount of means as the cañon is very steep and rugged, besides several places will be passed where snow-slides are of frequent occurrence.

In the winter and spring the same means will have to be provided in order to pass these places in safety at all times of the year. These slides are truly fearful things. Tremendous bodies of snow that start for a mile away, and gradually increase, and by the time they reach the bottom of the gulch they become impossible to resist, and sweep everything before them; yet, it must be remembered these places are very few in number, and I might say, there are but five places between here and Granite that are dangerous, and even these can be avoided, except in heavy storms, when neither life nor property are safe. Many suggestions have been made with regard to the best policy of fixing such places so that there will be no danger to the constant running of the cars.

Some think that the best policy would be to make cuts in such places, and then cover over with heavy timbers, that in case slides did come they would go on their course and harm nothing. This certainly is the safest plan, as nothing that could be built upon the surface would stand good against their force.

A Wire Tramway.

From a responsible man here, who has correspondence to that effect, I learn that as soon as the spring opens a wire tramway will be built, commencing at Grizzly Flat, and run to Granite. Mr. Hallide, of San Francisco, it is said, is the individual who intends building it.

One or the other, or even both of these enterprises, should be pushed ahead, as they are necessary for the development of the mineral wealth of this district. Although much doubt is expressed here about the possibility of a railroad being built, owing to the great amount of labor it will require and the roughness of the cañon, yet this is not an impossibility.

The railroad is needed as an indispensable necessity, especially for the safety of travel and the more rapid means of disposing of the vast amount of ore at the mines. By this means much of our low grade ore could be shipped to an advantage, which is now thrown away on the waste dumps, beside it will induce capitalists to invest, and thus aid in developing the country.

There is a whisper here that if the present parties who are now building the railroad do not complete the road in a reasonable length of time another company will be organized for this purpose who will not spare means or time for its speedy accomplishment.

The Christena Tunnel.

Owned by Dr. Vollum and others, of Salt Lake, is situated on the side hill a little west of the Grizzly mine, on the Davenport Hill. This tunnel was first commenced something over a year ago, and during the time has been worked at intervals. The length of the tunnel is 100 feet, where a shaft is being sunk, which is now down 45 feet, the contract being let for 80 from the top, where a rich deposit it is thought will be found, judging from other indications in that vicinity. Mr. John Murphy who has the contract, informs me that the rock is getting softer and not much trouble to blast, which is a decided evidence in their favor.

The Sherman Tunnel.

Belonging to an Illinois Company, 300 feet in,

is running to tap the Sucoor and State lodes, situated at the top of the Davenport Hill.

It is thought that it will take until the first of June to complete this tunnel, there still remaining two hundred feet yet unfinished. The Sucoor and State lodes are also the property of the above company, and are considered valuable property, each mine having a vein from eighteen to twenty inches of medium ore, with a small amount on the dump.

The Emma Hill Tunnel.

This tunnel, owned by Fred Fuller and others of Salt Lake City, is now in three hundred and forty feet, and running to tap the White Cloud, Southern Cross and Home Ticket, all owned by the same company.

The three leads just mentioned are in a line north and south, or nearly so, and not far from the Sucoor and State leads. The tunnel, in its course, will tap them all. The Home Ticket being farthest away. Fifty feet will strike the White Cloud, one hundred feet the Southern Cross and one hundred and fifty feet the Home Ticket. The latter is thought a very rich lead; in fact, it has quite a large vein, with considerable ore on the dump, only waiting to complete this tunnel, when work will be commenced in real earnest on these mines.

The Victoria and Imperial

Tunnel is a few hundred feet east of the last named, belonging to Mr. Washburn and company of San Francisco. Three hundred and fifty feet of this tunnel is now finished, and still they are driving ahead with three shifts, through a large body of lime rock, with earnestness, showing they are determined to find something that will pay for their labor.

Other Matters.

Several new slides have occurred in the neighborhood during the last week, but as far as yet learned no loss of life or property resulted.

The roads, owing to the late heavy fall of snow, have been blocked, except to footmen, but as the weather subsides twenty or thirty teams and a large force of men will reopen them again.

S. A. W.

Product of the Nevada Mines.

The product of the Nevada mines is one of great interest, and the *Alta* takes from the official returns a sort of history of the progress of the past two years. The assessment roll of the mines of Storey county, Nevada, gives the following product and value of the leading mines for the past two years to Dec. 31, 1872:

	1871.	Value.	1872.	Value.	Last yr.
Belcher.....	18,747	\$1,198,920	83,194	\$4,970,889	\$65.00

The average per ton of all the mines in 1871 was, it appears, \$27, and in 1872, \$32. This increase was mostly the result of the operation in the vast body of ore struck in the Belcher and Crown Point. If we take the quarterly figures of those two mines we have results as follows:

	1871.	Belcher.	Crown Point.	Pr. ton.
Quarter to	Tons.	Val.	Tons.	Val. ave
March 31.....	279	\$1,034	5,908	\$126,674 \$21.28
June 30.....	18,372	\$719,122 37.81
Sept. 30.....	2,829	212,038	17,240	\$266,650 30.68
Dec. 31.....	16,799	955,848	17,529	\$59,623 33.86
1872.				
March 31.....	20,698	1,071,350	19,121	\$1,030,149 53.42
June 30.....	21,932	1,203,037	35,183	\$1,759,748 50.10
Sept. 30.....	17,431	1,015,414	32,379	\$1,041,476 32.16
Dec. 31.....	23,133	1,604,868	24,079	\$787,478 32.79
Jan.....	8,601	437,495	16,000	\$210,450 41.43
Feb. 21 days.	7,822	460,493	10,479	\$324,474 62.00
Total, 1871.....	18,747	\$1,198,920	69,049	\$1,970,884 32.08
Total, 1872.....	83,194	\$4,970,889	110,762	\$4,598,849 41.60
1873, 62 days.	18,123	\$97,982	26,479	\$1,161,914 44.30

Grand total, 118,064 \$3,891,672 198,190 \$7,731,857

This table gives extraordinary results, showing the development of the body of ore common to the two mines. The Belcher until a few months since worked through the Crown Point, hoisting from the Yellow Jacket. The Crown Point first got its 1,200-foot level open just a year since, when the full mill power went on. The result was a production of \$1,759,746 in quarter ending with June. Then occurred several accidents, particularly the cave, which reduced the quantity of ore that could be worked, as well as the quality, since the cave matter could not be separated from it. In the December quarter the ore ran down to a low average, but the retimbering of the level was accomplished at an expense of \$150,000, and full operations have since been resumed. The ore in the 1,200-ft. level gradually rises in value as the cave matter is worked off, and the 1,300-ft. level is now adding richer ore to the mill supplies, and as the ore shows more gold, the value rises. The quarter to June 1, this year, will show 45,000 tons raised, of an average probably of \$60, giving \$1,000,000 more than the June quarter last year. The 1,400-ft. level is also nearly ready to tap. The Belcher is now operating upon the 1,300-ft. level through the Crown Point to the Jacket shaft, and the ore body there is immensely rich, and the production in that mine has given an average of \$55.05 in January and February. The results of the year's operations in the two mines must be immense.

DEWEY & CO'S
SCIENTIFIC PRESS
Patent Agency.

PACIFIC RURAL PRESS—Agricultural.
SCIENTIFIC PRESS—Mining and Mechanical.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others by reason of long establishment, great experience, thorough system, and intimate acquaintance with the subjects of inventions in our own community. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all civilized countries. The large majority of U. S. and Foreign Patents granted to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. ADVICE AND CIRCULARS FREE.

GOOD WORDS

—FOR THE—

PAIN-KILLER.

We can confidently recommend the Pain-Killer.—[Toronto Baptist.]

It is the most effectual remedy we know of for Aches, Pains, flesh wounds, &c.—[St. Johns News, P. Q.]

We advise that every family should have as effectual and speedy a Pain-Killer.—[Amherst N. S. Gazette.]

Our own experience is that a bottle of Pain-Killer is the best Physician a traveler can have.—[Hemilton Spectator.]

For both internal and external application have found it of great value.—[Chris. Era.]

A medicine no family should be without.—[Montreal Transcript.]

Could hardly keep house without it.—[Ed. Voice.]

Should be kept in every house, in readiness for sudden attacks of sickness.—[Chris. Press.]

No article ever obtained such unbounded popularity.—[Salem Observer.]

One of the most reliable specifics of the age.—[Old North State.]

Its power is wonderful and unequalled in relieving the most severe pain.—[Burlington Sentinel.]

An indispensable article in the medicine chest.—[N. Y. Examiner.]

It will recommend itself to all who use it.—[Georgia Enterprise.]

Is extensively used and sought after as a really useful medicine.—[Journal, St. John, N. B.]

No medicine has acquired such a reputation; it has real merit.—[Newport Daily News.]

One of the most useful medicines; have used it and dispensed it for the past twenty years.—[Rev. Wm. Ward, Assen.]

The most valuable medicine now in use.—[Tenn. Organ.]

It is really a valuable medicine, and used by many physicians.—[Boston Traveler.]

We always keep it where we can put our hands on it in the dark, if need be.—[Rev. C. Hubbard, Burmah.]

One of the few articles that are just what they pretend to be.—[Branislow Telegraph.]

In my mountain travels no medicine is of so universal application as Pain-Killer.—[Rev. M. H. Bixby, Burmah.]

24v25-1f

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.
For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the greatest number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.
They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.
The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Sellers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.
Millmen are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

Richardson & Co., Copper Ore Wharves, SWANSEA.

RICHARDSON & Co. have been for thirty years established in Swansea as Agents for the preparation, Sampling, Assaying, and Sale of Copper, Silver, Gold, Lead, Zinc and all other Ores and Metals, for which they have extensive Warehouses and Wharves under cover, 1,000 feet of Quay Frontage within the Floating Dock, and the most complete Machinery and Appliances. They are also prepared to make advances against Ores in anticipation of realization, and to guarantee all payments when required. 17v24-1y

LEA & PERRINS'
CELEBRATED

Worcestershire Sauce.

Declared by Connoisseurs to be the only good SAUCE
Caution Against Fraud.
The success of this most delicious and unrivalled Condiment having caused certain dealers to apply the name of "Worcestershire Sauce" to their own inferior compounds, the public is hereby informed that the only way to secure the genuine is to ask for LEA & PERRINS' SAUCE, and see that their names are upon the wrapper, labels, stopper and bottle.
Some of the foreign markets having been supplied with a spurious Worcestershire sauce, upon the wrapper and labels of which the names of Lea and Perrins have been forged, L. and P. give notice that they have furnished their correspondents with power of attorney to take instant proceedings against manufacturers and vendors of such, or any other imitations by which their right may be infringed. Ask for LEA & PERRINS' Sauce, and see name on wrapper, label, bottle and stopper.
Wholesale and for export by the Proprietors, Worcester: Cross & Blackwell, London, &c., &c., and by Grocers and Oilmen universally. 15v24-1f

EUCALYPTUS.

The attention of the Medical profession is respectfully called to the following preparation of this new remedial agent. Eucalyptus and its preparations have been found useful in obstinate cases of Intermittent and Marsh Fevers, often supplanting the use of Quinine. The paroxysms of Asthma and Catarrh are greatly controlled, and in various Kidney diseases and Catarrh of the Bladder it seems to act like a specific.

FLUID EXTRACT EUCALYPTUS.
This extract represents in a concentrated form the medicinal effects of the leaves of Eucalyptus Globulus.

THE ELIXIR OF EUCALYPTUS.
This compound presents the properties of the leaves in a palatable form and elegant appearance. Dose—One tablespoonful, to be repeated as often as the case demands.
Cigarettes of Eucalyptus Globulus, useful in Asthma, Difficulty of Breathing, Incipient Pleurisy, etc. Prepared and sold by JAMES G. STEELE & CO., Chemists and Apothecaries,
No. 521 Montgomery St., between Clay and Commercial, San Francisco. n28

SEARS, O. H. McKEE. 12-26-3m

WONDERFUL CURE.—A young man, a resident of this city, gives us the facts of the following remarkable cure. He says: "I suffered with Catarrh in its worst form. Bones came from my nose; my breath became offensive; I was compelled to eat alone. I had given up all hopes of being cured. At this time met Dr. E. V. EVOY, of Chicago, who had been cured by a remedy discovered by himself. I bought the remedy, with letters of faith, but the end of three months found myself cured." Our informant has now associated himself with the discoverer in the manufacture of the article, which will be known under the name of the Diamond Catarrh Remedy. Price 50 cts.; sent by mail for 60 cts. A. F. EVOY & CO., No. 9 Post Street, room 4, San Francisco. Sold by all druggists. 26v25-3m

EASTERN AGENT.—Albert H. Lewis, formerly of Atchison, Kansas, who has spent the past season in California, is now on the way to New York and other Eastern cities to represent the business of this office. Manufacturers and tradesmen who have the pleasure of an interview with him, can learn something of interest about California, and make favorable contracts for patronage of the several journals connected with this office.

No LIFE INSURANCE COMPANY has a better record or more permanently popular reputation than the CONNECTICUT MUTUAL LIFE INSURANCE CO. J. R. Roberts, 315 California Street, San Francisco, is the local agent for said company. Send to him for circulars and information of this reliable, first-class company.

And in accordance with law, and an order of the Board of Directors, made on the eighth day of January, 1873, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the sales room of Maurice Dore & Co., No. 327 Montgomery street, San Francisco, California, on the eighth day of March, 1873, at the hour of 12 o'clock m., of said day, to pay delinquent assessments thereon, together with costs of advertising and expenses of the sale.

CHAS. F. BALCOM, Secretary.

Office, 426 Montgomery street, San Francisco, Cal. te22

POSTPONEMENT.—The above sale is postponed until Monday, the seventh day of April, 1873, at the same hour and place. By order of the Board of Directors.

m15 C. F. BALCOM, Secretary.

Eagle Quicksilver Mining Company—Location of works, Santa Barbara County, California.

NOTICE is hereby given, that at a meeting of the Board of Trustees of said company, held on the 18th day of January, 1873, an assessment of fifty dollars (\$50) per share was levied upon the capital stock of said company, payable immediately in gold coin of the United States, to the Secretary at the office of said company, No. 302 Montgomery street, San Francisco, California. Any shares upon which said assessment shall remain unpaid on Wednesday, March 15th, 1873, shall be deemed delinquent, and will be sold at public auction, and unless payment shall be made before, will be sold on Monday, the 24th day of March, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. H. WATSON, Secretary.

Office, Room 5 and 6, No. 302 Montgomery street, San Francisco, Cal. te23

Imperatrice Eugenie Gold and Silver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Blue Mountain, Calaveras county, California.

NOTICE is hereby given, that at a meeting of the Board of Directors, held on the fifteenth day of February, A. D. 1873, an assessment of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, 712 and 714 Washington street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Saturday, March 23d, 1873, will be delinquent, and advertised for sale at public auction, and unless payment shall be made before, will be sold on Tuesday, the 24th day of April, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of Board of Directors.

GUSTAVE BERSON, Secretary.

Office, 712 and 714 Washington street, San Francisco, Cal. te22

Keystone No. One and Two Gold and Silver Mining Company.—Place of business, No. 507 Montgomery street, San Francisco, California. Location of works, Wallapai Mining District, Mohave County, Territory.

NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 10th day of March, 1873, an assessment of twenty-five (25) cents per share was levied upon the capital stock of the corporation, payable immediately in gold coin, to the Secretary, at the office of the company, No. 507 Montgomery street, San Francisco, Cal.

Any stock upon which said assessment shall remain unpaid on the fifteenth (15th) day of April, 1873, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the fifth (5th) day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

T. E. JEWELL, Secretary.

Office, No. 507 Montgomery street, San Francisco, Cal.

The California Powder Works

No. 314 CALIFORNIA STREET,

SAN FRANCISCO.

Manufacturers and have constantly on hand

SPORTING,

MINING,

And BLASTING

POWDER,

Of SUPERIOR QUALITY, FRESH FROM THE MILLS. It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market. We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

We also call attention to our

HERCULES POWDER.

Which combines all the force of other strong explosive now in use, and the lifting force of the BEAR BLASTING POWDER, thus making it vastly superior to any other compound now in use.

A circular containing a full description of this Powder can be obtained on application to our Office.

16v20-3m

JOHN F. LOHSE, Secretary.

BURLEIGH

ROCK DRILLS

—AND—

Air Compressors.

The Burleigh Rock Drills, which have stood the test of five years' constant use at the Hoosac Tunnel, and which are now in use in nearly every State in the Union, as well as in Europe and South America, are unequalled in efficiency and economy by any other Drilling Machine. They are of various sizes, and equally well adapted to Tunneling, Shafing, Open Cut or Quarrying, and will drill six to ten inches per minute in granite. They are driven by steam above ground. The Burleigh Air Compressor is the best engine yet devised for furnishing the "air motor" for the many purposes to which it is now being used.

They are to be used on the St. Gothard Tunnel, Switzerland; Tunnel 13 miles long. We refer to the following gentlemen and works:

Gen. Newton, U. S. A. Hell Gate Tunnel, L. I.
Mess. Shanley Hoosac Tunnel, Mass.
J. Dutton Steele Nesquehoning Tunnel, Pa.
Sidney Dillon Fourth Avenue Work, N. Y.
Col. Roebing East River Bridge Company, N. Y.

For further information, etc., address

L. C. PARKE,

VIRGINIA CITY, NEVADA.

BUY BARBER'S BIT BRACE,

PACIFIC BRIDGE COMPANY.

WORKS NEAR SOUTH POINT MILL, BERRY STREET, SAN FRANCISCO, CAL.

Are Prepared, with Superior Machinery, to Manufacture and Build all kinds of Bridges on Smith's, Howe's, and other Improved
Plans. Framing of all kinds done by Machinery.

The Smith Bridges have been thoroughly tested in the East for Three Years, and wherever tried have proved superior to any other
Bridge in the following points:
Being built of wood entirely, they are not affected by change of temperature.
The timber used is placed so directly in the line of strain, that less material is required to support the same load.
It is not perceptibly affected by shrinkage. It is the most Economical Bridge built. It is adapted to any practicable LENGTH OF SPAN.
Plans, Specifications and Terms will be sent to any County, Township or Person wishing to build a Bridge, and no charge made unless the
Plan is used. For all Public Bridges the Plan will always be open to competition.

Smith's celebrated CAST IRON PIER, economical, and adapted to heavy currents, built at low rates.

vantage than any other light heretofore tried, and at an
expense not to exceed five cents per hour. Lamps
furnished at short notice.

Letter of Recommendation.

Mr. C. B. Brown—Sir: Your Patent Lamp for light-
ing hydraulic mines, which you sold to me in December
last, has given entire satisfaction, and far exceeds my
expectations, and I think it the best and cheapest light
ever used to light mining claims by night, and am sat-
isfied that I have saved three hundred dollars by the
use of it in the last mining season over pitch or any
other light of the same brilliancy; and I will also say
that if I could not get another lamp, five hundred dol-
lars would not buy it. Yours,

W. D. APLIN.

Little York, Nov. 5, 1872.

For further particulars, address,

EXCELSIOR MINING PUMP.

2-MOUNTED.

No. 3-SHIP.

No. 5-MINING.

With six years use of this Pump we confidently recommend its

Use for Mining or Prospecting.

It is the CHEAPEST Pump in the market.

There is NO Trade Pump made of equal strength and power.

Every Pump is tested by hydraulic power to 125 lbs. to the square inch. So every Pump, large or small, is

WARRANTED

To Force Water 250 Feet High.

VALVE.

ALL PUMPS WARRANTED. All Expense of Transportation Refunded if the Pumps are Proved Defective.

Send for Circular.

Brittan, Holbrook & Co.,

HALLIDIE'S

Patent Endless Wire Ropeway.

Covered by Numerous U. S. Patents.

IMPORTANT TO

Mining Companies, Civil Engineers, Contractors, Etc.

The system of transporting material, such as Ores, from the mine to the mill, Earths for embankments, Rock from quarries, etc., by means of steel wire rope, has been well tested and found more economical, advantageous and reliable than any other method of transportation; and to the annexed certificates in connection therewith I beg to call the attention of those interested:

EUREKA, Nevada, July 10, 1872.

T. M. MARTIN—My dear sir: On your leaving for San Francisco, it gives me great pleasure to have you my written acceptance of the HALLIDIE TRAMWAY put up by you upon our mine in Eureka.

It is a perfect success, discharging ten tons of ore per hour with two men's labor. It is perfectly simple in construction, and, as far as I can judge, there is nothing about it to ever get out of order—nothing to wear out. While our requires but about two thousand five hundred feet of wire rope, I can see no reason why the line could not be extended almost indefinitely with equally happy results. Again, the carrying capacity might be doubled or quadrupled if desired. After several weeks trial upon our mine, the unanimous verdict of all who have seen it is a complete, unquestioned success. If this can be of any service to you, use it in any way you think proper. Very respectfully, C. C. GOODWIN.

EMMA HILL CONSOLIDATED MINING CO.,

Little Cottonwood, Utah.

Superintendent's Office, Sept. 23, 1872. T. M. MARTIN, Esq., Sir: The Ropeway constructed by you (HALLIDIE'S PATENT) for the Emma Hill Consolidated Mining Company, has been built in a most substantial and workmanlike manner, and is at this time in splendid working condition. I most cheerfully accept the work for the Company, and recommend it to others wishing a sure and speedy transit for ores over places impracticable for wagon roads, etc. Respectfully, L. W. COLBATH, Superintendent.

"The Vallejo works smoothly with the elevated wire tramway, which carries its load of ore as quietly and easily as if there was no winter or snow in the world. The objections to wire tramways may be on account of their cost, I have seen nothing yet that even approaches them in the facilities they afford for moving ore at all seasons of the year."—Correspondent Utah Mining Journal, Alta, Jan. 8, 1873.

The Vallejo Ropeway.

The Vallejo Tunnel Company's Tramway in Little Cottonwood, built on the HALLIDIE PATENT PLAN, is a complete success. It is between 2300 and 2400 feet in length, and is supported by thirteen stations. The fall in this distance is about 600 feet, and the wire rope, which is three-fourths of an inch in diameter, will safely and easily deliver one hundred tons in six hours. The machinery is automatic, loading and unloading the sacks or buckets. About one ton and a half can be sent down at one time. The stations are about two hundred feet apart, and the entire apparatus is strong and safe. As the wire rope is elevated about forty feet above the surface of the hill, the Tramway can be worked all winter long, without the slightest trouble. —Utah Mining Journal, Salt Lake, Sept. 23, 1872.

Mining Companies and others desiring to negotiate for the erection of this system of Ropeway, can communicate with me personally, or through Postoffice Box 904.

A. S. HALLIDIE, Patentes, 112 and 114 California Street, SAN FRANCISCO.

WIRE ROPE

For hoisting from mines, transmitting power, ship rigging, etc., of all kinds and sizes, on hand and made to order. Wire of all kinds and descriptions, furnished at lowest rates. A. S. HALLIDIE, 112 and 114 California St.

Warsop's Aero Steam System.

We present to our readers this week an illustrated description of a system in use in England which claims to protect boilers from scaling and foaming without the use of chemicals. Its efficiency was tested by one of our own citizens, who vouches for its merits. The principle of the system is to utilize the waste heat escaping through the smoke box by forcing compressed air through a coiled tube in the box; which air, thus heated to 600° Fahr., is forced with the water along the bottom of the boiler through a pipe perforated with small holes, at a downward angle of 45°, aiding ebullition. It is stated that by thus mixing air and water no incrustation can be formed, nor will there be any foaming. Although these advantages are conceded, theorists differ in the saving of fuel by aerosteam. The diminished consumption is attributed to diminished incrustation. The saving by use of aerosteam at English mines particularly is reported as very great, and it would probably be equally beneficial in this country.

Warsop's system has been practically tested on an engine on the Lancashire and Yorkshire Railroad, in England, for a year, and the results have satisfied the company so well that it has been applied to numerous other engines. The official reports of the practical working of the system on that road state that it prevents scaling, stops foaming, saves fuel, is cheaply applied to existing engines, and prolongs the lives of boilers, tubes and fire-boxes. It is stated that the engine on which it was tried was fitted out with only half new tubes, the remainder were old and incrustated with over one-eighth of an inch of scale. At the end of seven months' work it was found that the new tubes were clean and bright, and the old tubes were gradually parting from their incrustation. A curious atomic change in this scale was apparent, for it had become honey-combed and friable; portions had lost their adhesion to the tubes, came off in strips and were removed from time to time. The circular of J. L. Sanford, of this city, agent of this patent, whose card will be found in our advertising columns, states that it is found in practice that agitating the water by

the injection of heated air prevents incrustation in the boiler, keeps up a vigorous circulation of the water and maintains a uniform increase of force.

As to foaming the circular says that the engine was not only free from all interruptions of that kind, but the usual foam that floats in the water in the gauge tube was entirely absent. The water was so clear that it required close

The Coal Carrying Steamer "Eastport."

We spoke in a recent issue of a steamer called the "Eastport" having gone on a trip to Coos Bay to bring back coal, and at the same time stated that in case the experiment of bringing coal with steam power instead of sail was successful other similar steamers would be built. In view of this the following facts con-

There are three furnaces flues three inches in diameter direct to back connection, and 3¼ inch return flues.

Many engineers expected the boiler to be too small for the size of the engine and that too much heat would escape up the chimney. In proof that this did not take place and that the combustion was complete, the flues were found clean and did not require cleaning at the end of the trip; some wood chavings put into the smoke-box were found to be unconsumed. The evaporation was equal to 9.27 pounds of water to one pound of Coos Bay coal, a higher result than has ever been obtained on this coast in steamboat boilers.

The return trip was made in 48 hours with about the same conditions in the engine room, but with a light wind aft and without help from sails. Consumption of coal 20 tons; distance by log 451 miles. The success attending the trip of this vessel it is expected will induce the owners to place another on the stock and lay the foundation for regular freight by steamers. This will not only be a great convenience for getting coal to this city, but will give employment to many in building other vessels and running them. The "Eastport" is a very neat, handsome little vessel

aside from her utility, and a line of steamers of the same model running from here to Coos Bay would reflect credit not only on her builders, but on our city also.

GOLD IN UTAH.—It is stated that the heavy stratum of rich gold-bearing gravel known to exist in Bingham Cañon, Utah, in the old river channel, will be vigorously worked this season. The drain tunnel of the Young America Company is already eleven hundred feet in length, and will be continued with the aid of proper machinery. It is estimated that over a million and a half in gold has been taken from these mines during the past few years.

Kimball & Co., carriage manufacturers of this city, will send to Vienna a very elegant single-seated buggy, with running gear of plain varnished ash, and laurel-wood box, highly polished. It is made very light and some of those who see it will no doubt think Californians must be very reckless to ride in such a gossamer conveyance. It is, however, very strong and well made.

AERO STEAM SYSTEM APPLIED TO A LOCOMOTIVE.

inspection to see the gauge line. The system has been applied and thoroughly tested in marine engines with the same results.

It requires little argument to prove that if large quantities of waste heat are returned to the boiler through air tubes, there must be a great saving of fuel. From the official report on the working of this experimental engine, with half old and incrustated tubes, it appears that the average saving of fuel during the year from the first crude experiment to the last improvement, has been about 20 per cent. By the use of all clean tubes at this start and an improved air coil, better results are now said to have been attained. Before the system was applied the engine used 52.2 pounds of coal per mile, and now uses only 34.4 per mile.

The system may be cheaply applied to engines already built, the requirements being simply an air pump, a wrought iron tube coiled in the smoke box, a perforated copper pipe in the boiler, with connecting tubes and stop cocks, which additional parts may be seen by reference to the accompanying engravings.

cerning the first trip will be interesting. The "Eastport" left San Francisco on the evening of February 26th, during a severe southeast blow which lasted for 12 hours, raising considerable sea; from which time until Coos Bay was made they had moderate headwinds. Notwithstanding the ship was flying light she behaved well, and made the run—420 miles by patent log—in 58 hours, and consumed 23 tons of Coos Bay coal, developing 350 indicated horse-power, which is equal to 2.5 pounds of coal per horse-power per hour. The coal used was sound Eastport coal, but subsequent trials showed that good screenings could be used instead.

The engine is fully steam jacketed and is furnished with a good surface condenser which condenses the steam and allows the same water to be used over. During the trip up the waste amounted to only nine minutes feed from the sea. The boiler is made of the form most approved by English engineers for compound engines, and is 11.6 in diameter and 12 feet long.

CORRESPONDENCE.

Utilization of Placer Tailings.

[Written for the MINING AND SCIENTIFIC PRESS.]

Wherever the tailings from placer claims are hacked up, the soil thus made is the most productive of any known in the mining section, affording by its looseness the most favorable condition of vegetation and tree growth, no doubt owing in part to its permeability to moisture. But this does not include tailings from heavy hydraulic claims, this being generally clear sand and gravel.

The most valuable and productive garden spot in the mining section is made ground, and thousands of similar places abound whereby a small amount of labor, flats drained of their moisture and rendered barren by some ugly cut sluiced through in the search for gold, can be filled up and made valuable. In favorable locations it would even pay to sluice off from some steep hillside having a rich deep soil, to level these once fertile flats, now drained dry as a bone during our long summers.

In filling up a gulch—as in fact anything connected with improvement of the soil—the best way is the cheapest; construct a dam of two parallel walls of stone from two to four feet apart across the gulch and from bank to bank and fill in with soil well rammed down. However, well this may be done, there is always a strong probability, that when completed and filled, the water would find some place to leak through, and by the head acquired get a hole through, thus washing away the filling, if not undermining the walls themselves.

The best way is to back up the water by building up the dam, if not in too much volume, give the lower wall, considerable slope up stream and use as large a stone as can be handled in laying it, the larger the better, especially at the bottom.

If there is much water in the gulch it may be well to put in a long box, in the lowest place under the dam, and have a gate at both the upper and lower ends. The gate above to shut down and raise the water, to puddle the filling between walls, or to draw off the water in case of breakage; the lower gate shut above when all is finished would fill up with sand, but in any case it would be well that the stone work did not rest upon the box. When finished and up to the necessary level a ditch or by-wash should be dug around one or both ends of the dam, and continued for a sufficient distance below to prevent undermining, and of a capacity to carry off all heavy rains or surplus of water.

As placer mining has been the destruction and ruin of the best portions of the country where carried on, I call the attention of those making homes, to this method of partly repairing the damage, and in the long run will pay better than the ground originally mined out.

I. H. REED.

West Point, Calaveras Co.

The American Fire Detector.

[From our N. Y. Correspondent—ALBERT WILLIAMS, JR.]

This is a most ingenious contrivance for the detection and consequent prevention of destructive fires; for there hardly ever happens a fire which could not be readily extinguished in its inception. The great trouble has ever been that the fire is not discovered till under considerable headway; then it is a matter of great difficulty to control it. In view of this any sure method of finding out the fire and its exact location, instantly meets with a warm welcome. The "Detector," therefore, just fills a niche in our otherwise nearly perfect system of city fire departments; and where there are no engines, its protection is all the more necessary.

The only form of fire detector is that made by the "American Fire Detector Co.," under a patent issued Aug. 29th, 1865, to Mr. Dion of New York. It has been strongly recommended by the Board of Fire Underwriters, and is being adopted in all the large hotels, tenement houses, public buildings, etc., of that city. It is required by law to be placed in all tenement houses not provided with fire-escapes; and, in consequence of its less cost as well as intrinsic superiority, is generally preferred to the escape.

The apparatus is quite simple. The detector and alarm are distinct from each other. To quote the circular of the company:

"The fire detector in size and appearance resembles a small marine clock; the principle upon which the operation of this invention is based is that of the expansion of metals."

By means of a screw operating a hand upon the dial plate, a thermometric spring, composed of two metals, is set to the degree it is desired that an alarm should be sounded. When the temperature reaches that degree, the compound spring is, by the action of the heat, raised sufficiently to set free a weight which trips a lever in its fall, releasing an upper lever to which is attached to the wire connecting the detector with the alarm. When in use, the detectors are attached to the walls near the

ceilings, and the wire is carried thence, like an ordinary bell wire, to the indicator, annunciator or alarm, which is operated by tripping levers, each held suspended by a wire connected with a detector, or a number of detectors, there being one lever for each room or floor wherein the detector or detectors may have been placed."

The delicacy of the compound spring thermometer is something remarkable. It is much more susceptible to sudden change than the ordinary mercury or spirit ones, as it is not enclosed in glass, but perfectly open to the air. It is sometimes used in private houses to notify the hypercritical occupant when his furnace heat gets above the regulation, 68°. But for the actual detection of fires the gauge is usually set in the nineties, to avoid false alarms. If set only two or three degrees above the temperature of the room, the lighting of a match or the animal heat of one or more persons will release the alarm.

Though this invention has been in use but a short time, it has already demonstrated its value; and, without a single failure to alarm, has prevented many fires. Strange to say, the detector is used in hot houses, drying rooms, etc., almost as largely as for its original purpose.

Affairs in Eureka.

A correspondent writes us from Eureka, Lander county, Nevada, as follows:

Four months ago this was a prosperous mining community, our mines and furnaces were all running full blast, the hills resounded with the woodman's ax, on all sides were to be seen evidences of prosperity, which some deemed permanent. While I write, all this is changed, our furnaces are all shut down with one solitary exception—the Wild West, the mines are in the same condition except the K. K., the miners are thronging away to fresh fields of enterprise, and there is hardly a sound to disturb the stillness that broods over the land. You will naturally ask the cause of this sudden change. The causes are various. The Richmond, one of our leading mines, is shut down in consequence of their lawsuit with the Look Out; the Ruby Con. and other mines have stopped work from inability to have their ores hauled, owing to the horse disease, and several prospectors have ceased working their claims on account of the severity of the weather. As regards the Eureka Cons., the big mine of the district, everything is at a standstill. This inactivity I cannot account for. It cannot be in consequence of their suit with the Richmond, for they never took a ton of ore from the disputed ground; their reduction works are in good order, with a sufficiency of coal to last for some months, it is a well known fact among the miners that there is an abundance of ore in their mines, while the roads are as passable for them as for the K. K. Company.

Our correspondent then proceeds to give the details of certain differences between Superintendent Ellsworth and the miners employed in the Eureka Consolidated, which being of a local nature and of no special interest to the general reader, and which, moreover, having already appeared in a paper published in the immediate vicinity of the mine, we have omitted, to make room for matter of more general interest.

Letter from Julian District.

Our correspondent indulges, at the opening of his letter, in some fanciful theories with regard to the formation of the immense "mesas" or table lands of that portion of the State, which are not of general interest, and which he will excuse us for omitting and coming directly to the more practical matters which form the conclusion of his epistle.

This Julian district is notable as being the theater of a new class of development, resting entirely upon the result of labor unaided by capital, and we do not doubt that the mines in this vicinity will yet out yield any quartz gold mining district in the State. The owners are erecting their new steam hoisting works, and while excavating for the foundation laid bare two ledges, one of which works from \$10 to \$25 per ton.

The Golden Chariot has bought the Antelope mill and have their grade nearly complete so that they can move the mill to its new site, in the cañon four miles below the mine. Our prediction as to the turn out of this mine have been verified, and it will undoubtedly be the most immediately remunerative mine ever opened.

The Excelsior, situated about three-quarters of a mile southeast of the Julian, and owned by Dwarakowsky & Hauver, is down 70 feet, and is a "pocket" ledge; some of these nodules turning out hundreds of dollars in value to the shoveler.

The Good Hope, a supposed extension of the original discovery Washington ledge, is about to put on steam hoisting works. The California will resume work in May—this is undoubtedly a continuation of the Owens, and only requires going down upon to develop as well.

Upon the whole the prospects of a most prosperous future is opening for this part of San Diego County; there is but one cloud—the "grant," which hovers vulture-like over many of the best interests of our State.

F. M. SHAW.

San Diego, March 1st, 1873.

Mount Diablo Coal Mines.

We condense the following interesting items concerning the operations at the Mount Diablo Coal Mines, from a correspondence in the Brooklyn Home Journal:

A large amount of coal has been extracted during the past ten years, and the underground workings are now of vast extent, there being at the present time from five to six miles of levels or gangways in working order, independent of those abandoned and now caved. These levels are run across the breaks of the different veins at a distance of some 325 feet apart, from which miners work up through the breasts to the higher levels, cutting out the coal with exception of pillars left for support on either side of the gangways, and inserting timbers behind them as they advance to the upper levels, throwing the coal as sent into shutes about sixteen feet apart, down which the "bunkers" convey it to the

Lower Levels,

Along which it is hauled in rail cars, by mules or horses to the different stopes, up which the cars are hoisted by steam power, and then run off and dumped into the "bunkers" on the surface.

In these "bunkers" the coal is screened by some of the Heathen Chinese before being loaded on the steam cars for shipment, and in these "bunkers" is the only point at which our illustrious pagan brethren are allowed to work, so there are not enough of them paid to support a "Josh" at this point, while their Christian brethren are called on for contributions to send missionaries for their conversion abroad.

There are three different stopes now in use; 150x400 feet in width and 500 feet in length. A number of steam pumps and engines are at work at various points; while coal is obtained from

Six Different Lifts.

So you may imagine the operations are somewhat extended.

The company are now engaged in sinking a new shaft 19x9 feet in the clear, with two compartments for hoisting and one for pumping, said to be the largest and best on the coast, and now down 227 feet, designed to strike the upper vein at a depth of 400 feet; and the lower one at the depth of 800; to be continued to a much greater depth in the future at a depth of 217 feet.

A 12x15 Foot Tunnel

Which is 658 feet long, is being run from the shaft to intersect present workings on both veins.

A month hence two new engines will be purchased at a cost of \$25,000, which with cost of shaft to depth of 400 feet, is estimated at \$200,000, and when completed most of the present hoisting apparatus will be measurably abandoned.

About six years ago the company constructed

A Steam Railroad

Down through the cañon from the mine to New York landing, and the coal is now run from the bunkers into the cars and thence dumped on board of vessels at the landing, the cars running down the whole distance, under brakes, the descent being 767 feet, the heaviest portion of the grade being

300 Feet to the Mile,

The steepest up which locomotives are driven in the United States. Three locomotives are in constant use, principally for hauling up cars, freight and materials for the mine; two passenger cars, daily, being attached.

As I stated before, the present yield is from

3,000 to 10,000 Tons per Month,

And the company are prepared to throw that amount or more on the markets in the future, and our English cousins are hardly likely to prevent it by competition, as their supplies seem to be rapidly exhausting.

It will cost probably \$40,000 to place the new hoisting engines in position. They are on the

First Motion Principle,

A new introduction in this country. The drum revolves with each revolution of engine, taking up forty-two feet of rope, and capable of hoisting and discharging a load of one ton per minute, from a depth of 1,000 feet. The rope will be of English steel wire, tapering, and weighing two tons. The engines are being built at the Pacific Iron Works, San Francisco, under the superintendence of Mr. Frutter, engineer of the mine, and will be of 300 horse-power.

EXPLORATION OF AFRICA.—A dispatch from Berlin gives the following item: A thorough exploration of Africa, from the west to the east coast, has been under contemplation for some time, and it is believed that all preliminary arrangements for the success of the undertaking have been made. The geographical societies of Germany, who have had them under consideration, have adopted a plan by which they propose to complete from the west coast of Africa the discoveries made by Dr. Livingstone from the east coast.

MARSHAL'S SALE OF MINES.—The Monitor and Magnet mines, in Little Cottonwood Cañon, Utah, owned by an incorporated company in this city, were sold on the 12th inst. by the Territorial Marshal, to satisfy an execution for \$11,000. They were purchased by Theodore F. Tracy, agent for Wells, Fargo & Co.

Another New Mining Company Proposed.

We learn that some parties left Grass Valley this morning for San Francisco, the object of the visit being for the purpose of raising a capital of \$15,000 with which to work the Donaho and Ryan quartz claims. These claims are on the northwesterly extension of the Ophir (Empire Co.'s) and the Rich Hill ledges, being 1,000 ft. in length on the Ophir ledge and 800 ft. in length on the Rich Hill ledge. The claims are situated at the head of Woodpecker Ravine and are one mile in a southeasterly direction from Grass Valley. The proposition on which it is hoped that capital can be raised is as follows: A company will be incorporated, the capital stock of which will be divided into 20,000 shares of the par value of \$100 each. Of these shares, 10,000 (one half) will be sold at \$1.50 per share, a total of \$15,000. The present owners of the claims are to retain the other shares. The money thus raised will be used entirely in working the claims, such as erecting machinery, sinking a main shaft, etc. The claims are well situated and have only been worked to a depth of from 35 to 40 feet, and on a length of about 600 feet, which shows the pay chute to be quite a long one. The ore taken from these claims has paid, by mill process, from \$20 to \$75 per ton, never less than the lower figure named. The ledges in the claims are in thickness 20 and 10 inches; the Ophir or Empire being thicker than the Rich Hill. These claims we think, bid fair to equal, if not to excel the Empire mine in its palmy days of the year 1854, and with the improvements of the present day, in the manner of working mines and in the appliances for saving gold, the Donaho and Ryan (Magenta) claims will give the owners handsome dividends.

We regard the plan, briefly detailed above, of raising money with which to pursue the business of mining as a move in the proper direction. Instead of selling, or attempting to sell at large figures, for cash, let the owners of quartz claims retain a certain interest and give the other portion to those who will furnish working capital; the owners receiving no money for the claim until the claims themselves pay dividends. Worthless claims will thus be kept out of the market. Under such a plan there is no chance for deceptions and no inducement for misrepresentation. We hope to see other miners follow this plan, and if so the miners here will find plenty of employment. The good mines of this vicinity are great in number, and the owners of them will do well to take chausse with capitalists in making developments.—Grass Valley Union.

A HOAX.—Our Eastern contemporaries are being misled by an item which is going the rounds of the press, and has now got into the *Iron Age*, to the effect that Dr. Blake, of the San Francisco Academy of Sciences, and Judge Hastings, of the California State Geological Survey, announce the discovery of a current of electricity running north and south at a distance of about 150 miles from the Pacific coast, along a belt of metallic deposits, which serves as a conducting chain between the poles. The truth is that neither Dr. Blake nor Judge Hastings ever announced any such thing, nor has Judge Hastings the slightest connection in any capacity with the California State Geological Survey. Both gentlemen are members of the California Academy of Sciences and we heard one of them at a recent meeting, make some inquiries as to the author of the paragraph mentioned. Some one in this city wrote a letter containing the news (?) to an Eastern paper from which it has been widely copied. It was written in a spirit of fun, and probably, by the same pen that sent the Pavy hoax to the New York *World*, giving the results attained by the Pavy expedition at the Open Polar Sea, when Pavy had never left this city.

NEW COAL MINES.—Last evening it was rumored in the different Club rooms, and on the streets, that a large deposit, or a number of deposits of coal, had been struck in Box-Elder Cañon, about seven miles from here. What the kind or quality of the coal is, we are not informed, and, in fact, it is not known to the discoverers, who are a party of gentlemen residing in Brigham City. A party of gentlemen went down to Salt Lake City with some specimens of the mineral in question this morning, to have it examined, and we hope that although the substance may not prove to be the pure article, it will lead to a rich vein of black diamonds, which will be worth a mint of money to the discoverers as well as to the whole country generally.—*Corinne Reporter*.

DUTY ON IRON FLUES.—A case was on trial on the 12th inst., in the United States Circuit Court, to recover \$580.29, duty paid under protest. On the 25th of March, 1872, William McCrindle imported from Glasgow, Scotland, 925 wrought iron flues, weighing 58,029 pounds, upon which he claims the lawful duty was 2½ cents per pound; but ex-Collector Phelps charged and demanded 3½ cents, which Mr. McCrindle paid under protest. He appealed to the Secretary of the Treasury at Washington, who sustained the decision of the Collector. The difference is \$580.29, to recover which the plaintiff commenced an action in the Circuit Court.

SCIENTIFIC PROGRESS.

Is Heat any Mode of Motion of the Atoms of Ordinary Matter?

Prof. W. A. Norton, furnishes the March number of the *American Journal of Science*, with an elaborate discussion on this interesting query. With regrets that we have not space for the article entire, we append a statement of the points made in objection to the proposition, and the conclusion to which the author arrives. The Professor opens his paper with the following

Query.

Is heat any mode of motion of the atoms of ordinary matter; such atoms being regarded, in accordance with the common notion of an atom, as incapable of experiencing any change of form or dimensions, or in the intensities of their acting forces?

There are three conceivable modes of motion of such atoms—a vibratory or oscillatory motion, and a revolution of one atom around another; or a rotation of each about an axis.

The inquiry has reference only to atoms of ordinary or gross matter. There can be no question that heat, in its origin, and generally in its manifestations, consists in some form of periodic movement, attended with regularly recurring impulses communicated to the ether which fills all space and pervades the interstices of bodies; since waves of radiant heat cannot possibly have any other origin. But the question is, whether the constituent atoms of bodies have this movement, or those of some form of ethereal matter intimately associated with these atoms.

Can Heat be Any Mode of Vibratory, or Oscillatory Motion of the Atoms?

Against this notion of the origin, or nature of heat, many serious objections may be urged. It implies rates of vibration inconceivably more rapid than we have any independent reason to suppose can take place in the interior of bodies.

The most rapid molecular vibratory motion that we know of, occurs when a vibrating body emits a musical sound of the highest pitch that the ear is capable of detecting. This is at the rate of less than 80,000 vibrations per second, but an atom emitting the heat-rays of the red end of the spectrum vibrates at the astonishing rate of 455 millions of million times per second! Thus in the supposed heat motion the vibration is six thousand million times more rapid than in the most acute audible musical sound. It is true the disproportion between the quantities of matter in vibration in the two cases may be very great, but it does not follow that the rate of vibration should augment in the same proportion.

That this astonishing disproportion above stated, between the velocities of vibration of heat-rays and the most acute musical sound, may exist, it is necessary that the same enormous disproportion should subsist between the accelerating forces in operation.

That this may be true, it is also necessary that every substance should be an aggregation of molecules made up of infinitely smaller atoms, and that in every instance the distance between the molecules should be vastly greater than that between their constituent atoms, and that each molecule should consist of millions of atoms. It is hardly necessary to add that there are insuperable objections to this supposition, on both chemical and physical grounds. The author here goes into an elaborate discussion to prove that heat cannot be any mode of vibratory or oscillatory motion of atoms.

Can Heat Consist of the Revolution of Atoms Around Each Other?

The same objections that have been urged against the theory of atomic heat and light vibrations, will hold against this hypothesis, which seems, in fact, to be almost a mechanical impossibility, consistently with the ordinary permanency in the properties of substances.

Can Heat Consist in a Rotation of Atoms about Axes?

The same objections still hold against this hypothesis as against that of atomic vibrations, to which it may be added, that upon this idea the expansive action of heat must result from ethereal vortices originating in the motion of rotation, but if such vortices have an outward or repulsive action, in a direction perpendicular to the axis of rotation, the tendency should be the reverse of this in the direction of the axis; and hence atoms that have taken on, under the impulse of the heat waves, a more rapid rotation should exert an expansive action in certain directions, but a contractile action in directions at right angles to these.

Other objections, might be urged against the doctrine, drawn from both physical and chemical considerations, which, unless they can be effectively answered would seem to require that this doctrine must be unhesitatingly abandoned.

Conclusions.

The results then bring us irresistibly to the conclusion that atoms of bodies must be made up of distinct parts bound together by certain forces; and that heat must consist in some movement of relative displacement among these constituent parts of the atoms. If now we consider that every atom is capable of exerting upon surrounding atoms an effective re-

pulsion at the most minute distances, and an effective attraction at certain greater distances, we are led to infer that the "atom," so-called, consists of a central attractive nucleus, surrounded by an envelope, or atmosphere, composed of repulsive elements. We also readily discern the possibility that heat and light may consist in some mode of motion of this outer envelope, either in its elementary parts, or as a whole.

Now we have independent evidence, afforded by the entire series of electric and magnetic phenomena, that there exists a subtle form of matter, made up of mutually repulsive elements, intimately associated with the atoms of bodies, which has received the name of the electric fluid, or electric ether. It is true that it has been vaguely conjectured that electricity may consist in some mysterious mode of motion of the atoms of ordinary matter, but such a mere conjecture, unsubstantiated by any decisive evidence in its favor, cannot throw an air of improbability over an hypothesis that is sustained by a multitude of actual phenomena.

It is, however, conceivable that the electric may be identical with the luminiferous ether which permeates all bodies, and is known to be physically linked to its atoms. We may then form two possible conceptions of an atom, with its essential accompaniments, viz: (1) that it consists of a true atom surrounded solely by an atmosphere of luminiferous ether; (2) that it has, in addition, an envelope of distinct electric ether immersed in the ethereal atmosphere.

In view of the results of this discussion, we recognize the high probability that heat and light originate in some mode of motion occurring in the ethereal atmospheres, or in the electric envelopes of the atoms; or, more properly, in the force or forces by which such a movement is produced.

Against this conception of the origin and nature of heat, the objections that have been brought forward against the prevailing notion do not hold good. The source of heat is now transferred from the atom proper to its ethereal atmosphere, or electric envelope, one or both—and therefore to a form of matter nearly if not quite as subtle as the medium of light, and whose elastic forces are nearly or quite as intense. Hence the enormous rapidity of the recurring movements, and the amazing intensity of the accelerating forces in play in the evolution of heat and light, are in full accordance with the present hypothesis.

Again, the change in the physical state of the "atom" and consequently in its operative forces, which we have recognized as attendant upon the evolution of heat by impact, are effects that may reasonably be expected from a disturbance of the atomic envelope by the force of impact. Also, upon this hypothesis the impact of the ether of space upon the earth, and other cosmical bodies, should take effect upon the ethereal atmospheres of the atoms of these bodies, and develop electric or ethereal currents, that would eventually pass off in the form of heat-energy, without finally checking the transitory motion of the atoms.

WATER ON THE MOON.—All observations hitherto made tend to prove that water in any form does not exist on the moon's surface. But it has been considered that it was once present there, and indeed traces of aqueous or glacial action are by some considered to be evident. What then has become of the water? Assuming the solid mass of the moon to contract on cooling at the same rate as granite, its refrigeration, though only 180 deg. Fah., would create cellular space equal to nearly 14½ millions of cubic miles, which would be more than sufficient to engulf the whole of the lunar oceans, supposing them to bear the same proportion to the mass of the moon as our own oceans bear to that of the earth. If this be the present condition of the moon, we can scarcely avoid the conclusion that an ocean can only exist on the surface of a planet as long as the latter retains a high internal temperature.

VIBRATING MOTION.—Every one is familiar with the large amount of vibrating motion produced on the earth by a train of cars or a loaded team, when passing very near the observer; but few, however, can realize the fact that the movements of a horse, over pavements, even before the sound can be heard in the stillness of night, will cause serious disturbance to many instruments used by scientists in their observations. Prof. Tyndall describes an instrument which he was lately using in London, so delicate that the indicator would move through a scale of more than a hundred numbers by the mere passing of a cab. "In fact," he remarks "so sensitive is the instrument, that long before the sound of the cab is heard, its approach is heralded by the quivering of the figures on the scale."

STILL ANOTHER ASTEROID.—The discovery of the 129th planet or asteroid was announced some two or three weeks since as having been made by Dr. C. H. F. Peters, on the night of February 5th. And now we learn by an appendix to the March number of the *Journal of Science*, that Dr. Peters has announced still another—the 130th, as having been made by him on the 19th ultimo. It shines as a star of the 11th magnitude. These discoveries were made at the Litchfield Observatory, Clinton, N. Y.

A COMET was seen to traverse the system of Jupiter and his moons, in 1870, without causing the smallest disturbances among the satellites, although the nebulous body of the comet itself was so much disturbed that its entire orbit was changed.

BIELA'S COMET.—This remarkable comet does not seem to have completely lost its identity as a cometary body, as Mr. Poyson, the English Royal Astronomer, announces in *Nature* that he has received advices from Prof. Klinkersruef, stating that he distinctly saw at least one portion of that comet on the night of November 30th last. This vision being interrupted by clouds, he did not see it again until the 3d of December, when it showed "bright, with a decided nucleus, but no tail." The next morning he got a still better view of it, when it still showed a "bright nucleus; a faint but distinct tail." He saw but one comet—in fact, in the few moments available for observation, he had no time to look for the second comet. Thus the speculations with regard to the disruption of this body, and its separation into a cluster of meteorites must remain unsettled until its next appearance, at least—some three years hence. Prof. K. seems to think that the comet actually touched the earth on the 27th of November; as when last observed, the two separate bodies into which the comet is known to have been divided several years ago, being over a million of miles apart and still receding, it may be that one of the divisions only has become disrupted, and taken the form of a cluster of meteors.

MECHANICAL PROGRESS.

Joining Band Saw Blades.

The operation of joining band-saw blades, that at first seems so mysterious to those unused to brazing and soldering, is extremely simple when once learned. A few failures may be expected in the first experiments, and the letters received by the manufacturers of sawing machinery from their customers relating to this matter are sometimes quite humorous, and not unfrequently contain practical suggestions of great value, that have been overlooked in the workshop by the builders.

Brass, spelter, German silver, and various alloys are used for making the joints. The preference being generally in the end given to the silver solder, on account of its convenience and the low heat at which it fuses, compared with brass. Its strength is quite sufficient, although not equal to brass; in fact the joints, however made, rarely give way, the weak points being where the annealed or soft steel meets the tempered, or unannealed portion of the blade; by a little dexterity, however, and after some experience, the temper can be restored at this point, by applying water while the blade is yet hot, a plan that is now commonly practised.

Joining saw blades, however, belongs to the saw maker, and the necessity for doing it in the workshops is owing to the frequency of breaking the blades, which will no doubt be overcome in time.

To make a joint with silver solder or German silver, the solder should be rolled into thin sheets; the saw being scarfed or bevelled off to about one-third of its thickness at the ends, and cleaned with acid; the solder is placed in the joints, the piece being large enough to project on all sides; the joints should then be clasped with a heavy pair of tongs, heated to a full red heat, and held until the solder is well melted and runs out of the joint, when the tongue can either be suddenly cooled with water, or removed, as the case may be. For heavy saws of four inches or wider, there should be provided two pairs of tongs, the heated pair is clasped over the hot pair from the opposite side, and gives the compression needed to close the joint.

The manufacture of band-saw blades requires the most careful and intelligent manipulation, with a great deal of what may be termed special knowledge; so much so, that their manufacture has become quite exclusive things in Paris, where they are nearly all made at this time. The steel for the larger plates and indeed for the greater number of saws, is made now in England, but the tempering and smithing processes remain with the French.

Saw makers sometimes contract with French houses for steel, tempered and ready for toothing and grinding processes that can certainly be as well done, and much cheaper in France; the object being to secure the name of manufacturing band saws. This plan is likely to lead to doubtful results, owing to the great danger of drawing or injuring the temper by those who do not understand the entire process.

Perin Company of Paris, were the first to manufacture these blades that gave profitable results; being also the manufacturers of machines, and indeed for a long time the only manufacturers of such machines. Their experiences in operating the saws combined with great care and perfection in their manufacture, have rendered Perin's blades famous all over the world.—*Richards' Treatise on Wood Working Machines.*

IMPROVED BLAST FURNACE.—The Messrs. Neilson, of Summerlee, Eng., have recently put in operation a blast furnace, which is said to be working much more economically than blast furnaces of ordinary construction. The secret of the operation consists in the increased height of the furnace and the proper distribution of the gas generator. The diameter of the bosh is 16½ feet, the shaft rising 70, instead of 50 feet, the height usually allowed for that diameter of bosh. The furnace gradually elopes to a diameter of 12 feet at the top.

THE PRESERVATION OF EXPOSED SHEET-IRON.—The direction of the government railroads of the Netherlands has published the results of some experiments in regard to the preservation of sheet-iron used in railroad bridges. From 32 sheets half was cleaned by immersion for 24 hours in diluted hydrochloric acid; they were then neutralized with milk of lime, washed with hot water, and while warm dried and rubbed with oil. The other half was only cleaned mechanically by scratching and brushing. Four of each kind were then equally painted with red lead, with two kinds of a red paint of oxides of iron, and with coal tar. The plates were then exposed to the weather, and examined after three years. The result was, 1. That the red lead had kept perfectly on both kinds of plates, so that it was impossible to say if the chemical cleaning was of any use. 2. That one kind of iron oxide red paint gave better results on the chemically treated plate than on the other; in fact, a result equal to that of the plate painted with red lead, while the other kind of iron oxide red gave not very good results on the plates, when only scratched and brushed. 3. That the coal-tar was considerably worse than the paint, and had even entirely disappeared from those iron sheets which had not been treated chemically, but only cleaned by brushing.

TO REMOVE FAT FROM THE WATER OF CONDENSED STEAM.—The steam condensed from engines always contains fat, resulting from the material used for lubricating. Messrs. Cail and Co., in Paris, collect the water of condensation in a common reservoir, and pump it into a receptacle provided with a powerful stirring apparatus, consisting of shovels, Archimedian screw, etc. This receptacle is three-fourths full, the remaining space being filled with petroleum; the apparatus is set in motion for five minutes, the water being allowed to settle fifty-five minutes. Five minutes time is sufficient to separate all the fat which is then contained in the oil, and the purified water can directly be used again. A hundred pounds of petroleum will absorb fifty pounds of fat; it has then a specific gravity of 0.840, but should be renewed when presenting a density of 0.810. It is subsequently regained by distillation.

SILICON STEEL, to which we have several times referred, seems to be steadily making its way into practical use. Its manufacture has been patented in England. The *Journal of Iron and Steel*, in speaking of it, says: "The pig iron from which it is made is melted in a suitable furnace, and when nearly melted, an addition of from 15 to 40 per cent. of its weight of silicious magnetic iron ore, mixed with coke, is made, and well stirred into the metal, after which it is run out into pots and placed at the side of the furnace, holding about half a ton each, in which it is well stirred up with a rabble, previous to being tapped into the moulds. If wrought silicon steel is required, the same process is followed out, with only the difference, that when the steel is in the pot, it is stirred up until it "balls up," or comes to nature, as it is termed. Silicon steel, when of good quality, is stated to contain 0.600 per cent. carbon, along with 0.552 per cent. silicon.

CUTTING TOOLS OF COPPER.—It has been doubted by many that the copper tools of the ancients really possessed the density and cutting power usually ascribed to them. Sir Gardner Willkinson, however, remarks that some of the bronzes daggers found by him in Egyptian tombs were so beautifully tempered that, after having lain buried for 3,000 years, they possessed, when dug up, an elasticity almost equal to that of steel. It is thus definitely proven that the Egyptians really did possess an art, which has been lost, of making bronze of a particularly fine temper, capable of taking and keeping a sharp edge.

PRIZE FOR STEEL.—The Council of the Society of Arts, London, have resolved to offer the gold medal of the society to the manufacturer who shall produce and send to the London International Exhibition for 1873, the best collection of specimens of steel suitable for engineering purposes. The council reserve the right of withholding the premium, in the event that the premiums exhibited are not meritorious.

THE MANUFACTURE OF RAILS by a new system, which does away with manual labor to a great extent, is to be carried on in a rail mill, which is now being erected at Louisville, Ky., at a cost of \$500,000. In the process of making the rail, the iron passes through thirteen sets of rolls, without a halt, and is turned over five times for side rolling. The iron is taken from the heating furnace, and transformed into a rail in half a minute.

A NEW FUEL FOR WARMING CARS.—On some German railways the carriages are heated, without stoves or hot water pipes, by the use of a composite fuel, which emulsifies slowly; being placed in an iron vessel, which is enclosed in a copper box, hermetically sealed. In case of accident all danger of accident is thus obviated. The contrivance will yield a steady supply of heat for twenty-four hours without recharging.

RESISTING OXIDATION.—It is said that Mr. Rhind found in a tomb at Thebes, which had probably not been opened for 2,000 years, iron hoes and nails on the doors of the repositories "as lustrous and as pliant as the day they left the forge." How were they kept from oxidation?

TUOLUMNE COUNTY.

MINING AT ASTRAVILLE.—Tuolumne Independent, March 15: The claims in and around Astraville, above Cherokee, are good. The Wild Cat Co. have their shaft down 90 ft., and tunnel 75 ft. long. The vein is 18 inches to 2 ft. wide and pays \$10 per ton. The Co. have in astraville, and intend to put up a five-stamp mill shortly.

The Easton claim looks well. The rock is rushed by two stamps at present, and ground by an arrastra.

The Uncle Sam and Virginia claim have a shaft down about 100 ft. The rock pays \$60 per ton.

Nevada.

ANTELOPE DISTRICT.

LOCATION.—Eureka Sentinel, March 15: This district is located 2 or 3 miles east from Chinney Station, extending north to Mount Ararat and south to Sulphur Lake, and about 5 miles east and west.

This district divides itself into two zones or belts. The metallic field of one is in a fine granulated silicate of lime the other is in dolomite, or magnesian limestone, containing a variety of lead ore.

A MORTEN VEIN.—One great mother vein divides the district into nearly equal parts; it runs north and south, and dips east.

The Indian Queen.—Upon which an inclined shaft being sunk is a mine of fine plumbago. The gangue contains gold, as well as silver, and assays \$175 in silver and \$35 in gold, or \$210 per ton. Gold can be seen with the naked eye in some of the rock.

AN OLD FORTY-NINER.—Evening Star, Merrihue, Monitor, Kearns, Alabama, Caledonia, and Highland Chief series of mines belong to Donald McMurtry, an old 49er, who has done a great deal to develop the mineral wealth of the country.

CHINA MINES.—The Whelan boys own the General Jackson, Enterprise, and Ophir. These mines look well; assays ranging from \$80 to \$240.

JOHN ROACH is the owner of the Native Silver. This belt is impregnated with chloride of silver; a fine foot vein is in sight. A shaft is being sunk; and from appearances, this is a promising mine. It contains large ore bodies.

THE WAVE, in which a tunnel is being driven to tap the ore body, is 90 ft. deep.

Washington has a shaft 10 ft. down in chloride, assaying from \$85 to \$100. This has the appearance of being large mines.

BELMONT.

BELMONT CO.—Reese River Revue, March 15: After the Canfield incline by contract, having let 100 ft. They are stopping on the water level and are working on the best body of ore ever discovered in the mine. This body is 700 ft. north of the Canfield shaft, already measuring 80 ft. along the drift, showing a face of 5 ft. of ore that will average \$300 per ton.

EL DORADO CON. CO.—This company have commenced stopping on 340 ft. level north; working in an immense body of black sulphurated ore, assays from which run from \$130 to \$1200 per ton, also stopping on 240 ft. level north and south, and raising a chute from 400 ft. level north, 150 ft. from main incline. The ore house and dump are filled up with good ore, which is accumulating on account of the mill being occupied this month on ore from the Arizona mine, which is keeping the mill going from its fine breast of ore on lower tunnel level. The company is shipping at the rate of \$2,000 worth of ore daily.

MONITOR CO.—Keeping their mill running steadily on ore from the Monitor mine. All the upper stopes look well. The lower works are sending out some very fine ore. This company is shipping its regular quota of ore.

EL DORADO NORTH CO. have sunk their vertical shaft 50 ft. and are now timbering the shaft, which is 5 ft. 6 in. After the shaft is timbered up, a level will be run to the ledge 100 ft. below the bottom of the old incline.

ELY DISTRICT.

RICH ORE.—Pioche Record, March 8: We were last evening shown some very rich ore from the Khedive mine. It is the genuine chloride ore, and assays from 1,200 to \$1,500 a ton. It came from a vein-body one ft. wide; but the ledge proper it is claimed, is 20 ft. in width.

RICH DISCOVERIES REPORTED.—March 15: Last Saturday some prospectors came in from the west, bringing remarkably rich specimens of silver ore, which they say they obtained in the southern part of Esmeralda county, near the California line. The ores are chloride, for the most part. The discoverers say the veins are of great extent, some being 25 ft. in width.

HERCULES.—Pioche Record, March 8: There are 1,500 tons of ore on the dump of the Cave, the average assay of which, by careful testing, is \$190.15—\$150.12 silver, 7.55 gold, and \$22.40 lead. And there are also in sight in the mine at least 10,000 tons, which can be extracted, it is estimated, at \$1.50 per ton, neither blasting nor hoisting being required in the extraction.

PIOCHÉ PHOENIX.—The new shaft is down 350 ft. The rock very soft, the contractors making 4 ft. every 24 hours.

SILVER PEAK.—Work of sinking the incline was discontinued yesterday, at a depth of 210 ft. At that point the drift was started to the west through a good ore body, the vein matter is 4 ft. wide, 15 inches of which is good milling ore.

PIOCHÉ.—The usual amount of ore is coming up out of the Pioche and the amount at the dump piles is immense—much of which is high grade.

EXCAVATION.—This mine is turning out more ore than ever before, and it is of unusually high grade. The up assay averages \$150 to the ton. The main shaft is 200 ft. deep, and sinking will continue 10 ft. further, when a new level will be started to strike the ledge. The vein body from which ore is being extracted is about 2 ft. in width, well defined and dipping regularly at about 80 deg. to the southward.

RAYMOND & ELY.—From 75 to 100 teams are now engaged hauling ore to the mills from this great mine. The mine never looked better in all parts than it does today.

HOHN & HUNT.—No ore being extracted at the present, or the reason that the dumps are all full and vast quantities are delivered ahead of the mills.

CROWN POINT EXCAVATION.—The ledge in the bottom of main shaft continues to improve in richness—now down 10 ft. below the 90 ft. station.

GOLD MOUNTAIN.—Cor. Elko Independent, March 15: These mines are situated in the southeastern part of the State, near what is known as Lida Valley.

The ledge varies in width from 1 to 6 ft. except most of the gold lodes which are small and range from 2 to 4 inches. The State Line is the largest and best defined, being 7 ft. in width and cropping out for a distance of 1000 ft. Three shafts have been sunk upon it, showing well defined ledge in each. This ledge yields nothing at gold ore, and the precious metal is distributed very evenly throughout.

Two of the prominent silver leads are the Austin and Independent. The Independent is about 5 ft. wide, used in granite and has a streak of very rich ore, about 1 ft. thick, extending from the surface to the bottom of the works, a distance of 20 ft. Assays from this mine run from \$100 to \$2,000 per ton; the rock as taken out will work \$400 to the ton.

In Lida Valley they have a little 8 stamp mill, with only 4 stamps running. The Lida mines are in limestone, and the ore pays from \$100 to \$800 per ton.

IMPORTANT NEW SILVER DISCOVERY.—Pioche Record, March 14: Some important new discoveries of silver have been made in Long Valley District, about 50 miles

south of Bullionville. We have examined sample ore from one of these new ledges, the Green Monster, which must not be confounded with the Hiko vein of the same name. And it is one of the finest specimens we ever saw. With considerable chloride of silver it carries a small percentage of copper, and all the assaying tests, so far have run up to the hundreds per ton, while the selected rock has reached as high as \$2,700. The ledge is enormous in extent, being from 7 to 10 ft. wide, and it has been clearly traced 2½ miles. A shaft has been sunk 50 ft., and the ore body disclosed at the bottom 16 ft. wide and is remarkably rich. The ore of Long Valley seems to be free milling ore.

HUMBOLDT COUNTY.

SURFACE MINING.—Silver State, March 15: Some miners have commenced ground sluicing for gold in Congress Gulch, and, we understand, are making wages at the business. One specimen worth \$2.50 has been found in the diggings. Should the diggings prove rich, there will be plenty of water in the creek this spring to supply several mines.

MARIETTA.—The ledge in the face of the lower drift is 4 ft. thick, 1 ft. of which is solid ore.

STAR DISTRICT.—The De Soto mine, in Star District, is at present yielding richer ore than ever before. It resembles the antimonial sulphurets of the Shiba. Four or five men are employed in the mine, and it is estimated that the ore extracted daily will average \$100 to each of the miners.

SANTA CLARA DISTRICT.—Work progresses on the Lady Anna mine, and the prospects are encouraging. The character of the ore changes as depth is attained on the ledge from chloride to black sulphurets.

LANDER COUNTY.

GALENA.—Reese River Revue, March 12: The town of Galena is situated in Battle Mountain Mining district, about 16 miles southwest of Battle Mountain Station. The ore taken out in that vicinity is principally copper and argentiferous galena, large quantities of which are shipped every month to Swansea for reduction.

VIRGIN AND LAKE SUPERIOR MINES are situated in Copper Canon, and belonging to the Battle Mountain Mining Company, incorporated in England, ship monthly over 200 tons of high grade copper ore.

ANTIMONY.—The shaft is down 225 ft. at which depth is a 6-ft. ledge of antimony. We understand, however, that the ore pays a fair profit over the expense of mining and transportation.

WHITE AND SHILOH CONSOLIDATED.—This shaft is down 300 ft. at the bottom of which is a ledge 15 ft. in width, containing a vein between 3 or 4 ft. in width of galena and silver ore, carrying a large amount of ruby and wire silver. These mines ship about 100 tons of ore per month. The last shipment averaged \$550 per ton in silver besides the lead.

THRIFTY.—The shaft is down 175 ft. The proprietors are shipping 175 tons per month. At the depth attained the ore vein is nearly 3 ft. wide.

BUENA VISTA AND BATTLE MOUNTAIN.—Situated in Galena Canon. About five tons of fine ore are being taken out daily from the Battle Mountain—about 200 tons from the surface.

WASHOE.

Gold Hill News.—March 15, has the following:

HALE & NORCROSS.—The north, or engine winze, from the 1,500-foot level, made the connection with the main north drift on the 1,700-foot level at three o'clock a. m. last Monday, giving a splendid circulation of pure air and greatly facilitating the work in that portion of the mine. The main north drift is still continued, being 20 feet north of the winze and 180 feet north of the main incline. Four cross-cuts have been commenced on this level, one running directly east from the incline, another 80 feet further to the northward, also running east, and one running east and one west, directly from the engine winze, 160 feet north from the incline. A raise has also been started on the rich vein of ore struck while opening the 1,700-foot station, which opens out about three feet in width of ore, worth \$100 to the ton. The south drift at this station is being pushed ahead with all the vigor possible and nothing new to report. The ore breasts between the 1,300 and 1,400-foot levels are looking and yielding finely as usual. The ore body at the second station is opening out handsomely and promises a valuable development. The daily yield could be considerably increased, but owing to the horse disease it is impossible to get the ore hauled to the mills, so that only 160 tons per day are being extracted—just enough to keep the Bacon and Trench mills running, these mills being connected with the mine by railroad.

GOULD & CURRY.—The supply of water in the bottom of the incline has been steadily increasing for the past two days, impeding the work to such an extent that it is deemed best to stop the sinking until the pump can be lowered to the 1,700-foot station, which is ready to receive it, so that the delay can only be of a temporary nature. A drift north from the main east drift on the 1,500 foot level has been started on the ledge recently developed on this level, in the hope of finding ore further to the northward. The main south drift on the 1,600-foot level, to connect with the south drift from the Savage, is still pushed steadily ahead, with no change of consequence to note. Prospecting on the other levels continue as usual, with no new developments to note.

Letter of the 17th says that since the last report work has been stopped in the bottom of the incline, on account of the water increasing so fast that they could make no headway. The water was so hot they could not work in it, the thermometer showing 138, which is much hotter than heretofore shown on the lead. Will soon have the new pumps down and we will then continue sinking on the incline. On tenth station, east drift, have been running around the broken ground so as to get started to work on the quartz. Have made 26 feet, and expect to get into the quartz in a day or two. Have made 18 feet with the north drift. On eleventh station south have made 16 feet, with no change to report from any quarter.

CONSOLIDATED VIRGINIA.—The main north drift on the 1,167-foot level from the Gould & Curry shaft is making good headway, running on the east line of the ledge, the face of the drift still in ore. A cross-cut west (No. 4), 100 feet north from the last (No. 3), has been started for the ledge, and is in 20 feet, having about 8 feet further to run to reach the ledge.

About 23 tons of ore per day is extracted, which mills from \$33 to \$35 per ton. The shaft is down 247 feet below the 500-foot level, the bottom in good blasting ground, and the sinking progressing at the rate of about 3 feet per day.

By a private dispatch from Virginia we learn the following: "The Consolidated Virginia have cut a fifteen-foot ledge on the line of the White and Murphy and California. Assays run from \$64 to \$105 per ton."

WOODVILLE.—The south drift, third station, is 125 feet, showing a three-foot ledge of good milling ore. This winze from this first station is down 42 feet, the ledge in the bottom showing the entire width of the shaft. Commenced shipping ore to the mill last Sunday, but owing to the prevailing horse disease, was compelled to stop hauling on Monday evening.

YELLOW JACKET.—The main drift east from the incline at this 1,500 foot level is still driven ahead in the vein, with the face in lively quartz, principally. Owing to the great heat the progress is necessarily slower than it would otherwise be. Considerable water is met with, as the strata of the vein are cut through, but it is easily kept out with this pump. At the 1,400-foot level the drift north is continued, with the face in porphyry and quartz, which give low assays. The same may be said of cross-cutting at the north end of the 1,300-foot level. Forty or fifty tons a day of ore from this 1,300-foot level of the Belcher mine are hoisted through the Yellow Jacket shaft for that company.

CHOLLAR-POTOSI.—No ore is being extracted from this mine at present, the ore dumps all being full, and it being impossible to get the ore hauled to the mills. The northwest prospecting drift at the ninth station is still driven energetically ahead, with no change of material interest to note. The heavy flow of water from the face of the northwest drift at the eighth station still continues, keeping the pump steadily running, and greatly impedes the progress of the work.

SIERRA NEVADA.—Daily yield sixty-five tons of ore, keeping this mill steadily running. The ore breasts in the different parts of the mine are not looking quite as well as at our last report, although the value per ton remains unchanged. The use of coal instead of wood at the mill and hoisting works is found to work well, and quite a saving in the matter of expense. Prospecting the 500-foot or lower level still continues, with no important developments to chronicle.

BALTIMORE CONSOLIDATED.—The second station is now in sixteen feet and timbers for that distance. As balance hob for the pump will have to be put in at this point, taking some time, the sinking of the main shaft is being pushed forward as usual. The epizootic does not interfere with the working of this mine, there being plenty of wood and coal on hand and the work energetically pushed forward.

SAVAGE.—The two east cross-cuts, started last week on the 1,600-foot level have not yet made any valuable or important developments. Two other cross-cuts to the westward were commenced on this level during the week, but have not yet disclosed any change in the formation worthy of note. The main south drift on the 1,700-foot level is still pushed ahead with all the vigor possible, and no change to chronicle since our last report. The main north drift on the 1,600-foot level, to connect with the south drift from the Gould & Curry, is making good progress, having only about 170 feet further to run to make the connection.

The weekly report for the week ending on the 15th gives the following summary of operations: Ore extracted from the mine, 284 tons, 1,980 pounds; shipped to the mills, 134 tons, 1,980 pounds; on hand at the mine, 285 tons; average assay value of the ore extracted, \$24.36. The ore extracted came from the second station of the north mines.

SILVER HILL.—The water has been drained and sinking of the shaft resumed, the work making good progress, though some trouble is yet experienced from pockets of water. Work in the main north drift at the first station is resumed, the face of the drift still in excellent ore and making good headway. The main north drift at the second station is being driven energetically ahead, with no change of consequence to note.

CALEDONIA.—Work has been suspended in the main south drift on the 400-foot level, on account of the heavy increase in the flow of water. Cross-cutting and prospecting still continue in the main north drift on the 400-ft. level, with no new developments to note. The main west drift on the 500-foot level is in 60 feet, the rock in the face working well and excellent progress being made altogether.

NEW YORK CONSOLIDATED.—The water has been drained from the shaft and sinking resumed. The rock in the bottom blasts well, and excellent progress is being made. Everything in and about the mine is working well, and the energetic manner in which the work is being conducted by the present management, augurs well for its future prosperity.

BELCHER.—Daily yield 450 tons. Main incline down 76 feet below the 1,200-foot level. The 1,300-foot level still continues opening out finely. The cross-cut east from the main south drift, about 100 feet from the Crown Point line, is in about 50 feet. The last few feet it was not looking quite as promising as was expected, but to-day the face shows decided improvement, being in fine ore. The main ore breast at this level are showing splendid. The other ore producing levels above are also looking and yielding well as usual, and the billion yield for the present month promises to be even

better than that of last month. There is sufficient ore in sight to considerably more than pay for the snail's mine at the present price.

CROWN POINT.—Daily yield 600 tons. The quality of ore taken from the lowest levels shows considerable improvement, running higher in gold. The 1,300 foot level, especially, is turning out very fine ore. At the south line, next to Belcher, the best and richest ore is found. It is being worked six or eight sets of timbers wide, and the whole face is in first quality ore. The north drift has been discontinued. The south drift, at the 1,400-ft. level, and also the incline, is being driven ahead as usual. The mine is, like the Belcher, selling at considerable less than its actual cash value. The receipts for this present month are expected to foot up to fully \$1,000,000 or more.

IMPERIAL.—Work on the new machinery and other surface improvements is making steady progress. During the week the new pump engine was started up, everything working with the most perfect satisfaction. The pumps are being lowered in the shaft, and everything arranged in the best possible working order. Prospecting has been resumed on the lower levels, but as yet there are no rich developments to report.

KENTUCK.—Prospecting this 1,300-foot level still continues with no new developments to report.

OVERMAN.—There is but little change to report in this mine, with the exception of a steady increase in the flow of water from the face of the main west drift on the 1,000-foot level. About thirty-one feet have been added to this drift during the week. The pumping machinery is working splendidly, keeping the supply of water well drained.

SECOON.—This main east drift from the new shaft in the cañon is still driven ahead, with but little change in the quality of ore since our last report. The raise from this level to connect with the old upper works is pushed steadily ahead, this face still in ore. Nothing doing at the new shaft yet.

BUCKEYE.—Owing to the horse disease preventing any further ore hauling at the present time, the mill is stopped, and also all work at the mine, except a prospecting drift or two. The pump is kept going in order to keep the water out, so as to go ahead with the ore production when practicable.

ALAMO.—The main west tunnel is making good progress, the rock in the face working tolerably well. Sinking the shaft is making good headway, the quality of the ore gradually improving as greater depth is obtained, and the body widening out until it now fills the entire size of the shaft.

KICKERROCKER.—The water tapped last week has been drained and the main west drift repaired to within a few feet of the drift. As soon as the repairs are complete work will be resumed in the drift, with fair prospects of speedy and valuable developments.

SENATOR.—After starting up last week it was found necessary to make some repairs to one of the compartments to the shaft, which is being done with as much expedition as possible. As soon as the repairs are completed, sinking the shaft will be resumed.

ARIZONA AND UTAH.—The new machinery is nearly ready to start, and everything in and about the works will soon be in splendid working condition, so that the development of the mine can be prosecuted with all the vigor possible.

OCCIDENTAL.—A cross-cut west from the main north drift is in 22 feet in ledge matter, but has not as yet disclosed any ore. The main drift is still continued to the northward, with no new development to note.

MINT.—The shaft is down 112 feet. The contractors completed their work this morning, and it is the intention to immediately start a drift eastward to cut and prospect the ledge.

JULIA.—Good progress has been made during the past week in the east drift 800-foot level, and west drift 1,000-foot level. The water does not interfere with the work in either drift.

PICTOR.—Cross-cut 16 feet in rather low grade ore. Ore in incline shows improvement as sunk upon. Work will start in lower tunnel in a few days.

SUTRO TUNNEL.—Total length 3,700 feet. Work is discontinued in all the shafts, but the tunnel heading is being pushed ahead as usual.

JACOB LITTLE.—Work in upper mine and lower tunnel progressing as usual, with no new developments to report.

LEO.—Incline sinking as usual, with good progress. Some very good ore is coming from the vein.

GLOBE.—The two cross-cuts started fifty-five feet up the raise from the main tunnel are both still in good ore.

Montana.

GOLD CANON—RICH STRIKE.—Deer Lodge Independent, March 8: Jones & James have struck it rich on No. 5 above discovery. Their shaft is 33 ft. deep, and they have 14 ft. of rich, auriferous gravel, and prospects as high as \$1 to the pan have been obtained at 10 ft. above the bed-rock. They are preparing for systematic work next summer, and expect to realize from \$200 to \$300 to the set of timbers. About 30 claims have been located in the district, but only six have been opened, owing to the great depth of the ground.

MINERS are leaving Pioche for Wallapai District, Arizona, from which place recent rich discoveries are reported.

SALT LAKE BULLION.—The Salt Lake shipments from March 9th to 15th were three hundred thousand pounds of ore and one hundred and eighty thousand pounds of bullion.

The Fairfield Mine.

The new mill owned by C. G. Hneey, Baxter & Co., at Fairfield, Camp Floyd, is now in successful operation. It was first started up two weeks ago and already about thirty tons of ore from the Queen of the West, at Lewiston, have been treated, yielding an average of about \$200 per ton, at the clean up. The hullion is nine hundred and ninety-five fine, which is an extraordinary degree of fineness.

The system adopted is dry crushing by the Dodge Crusher and Pulverizing by the Attrition mill. From thence the pulp is taken to the Dodge pans, then amalgamated and flowed through the Dodge settlers, which collect all the quicksilver that may possibly pass off in the pulp from the pans. The process works to perfection—the results averaging about ninety per cent. of assay value. About ten tons of ore can be readily worked a day, and the engine power is abundant for double the amount of work. The mill is running entirely on the ore from the Queen of the West mine, which gives free milling ore, owned by a Detroit joint stock company. The mine has a thousand tons of ore on the dump, and about twenty tons a day can readily be extracted, so that the mill will run for any length of time. Altogether the mill and mine are turning out splendidly and will help the district immensely.—*Utah Mining Journal.*

Bullion Product of 1871.

Advance sheets of the Report of the U. S. Mining Commissioner for the year 1871 has been placed in our hands. The report will probably be issued in a few weeks. Among other things of interest to us here are the figures of the bullion product, which we will produce for the sake of comparing them with those furnished by Mr. Valentine, of Wells, Fargo & Co.'s Express, from which they differ materially. The latter statement, which is carefully prepared at each of the companies' offices, showing the amount shipped monthly during the year, was as follows:

State or Territory.	Silver Bullion or Amalgam.	Gold Bullion or Amalgam.
Arizona.....	\$ 163,739 93	\$ 163,739 93
British Columbia.....	1,349,580 83	1,349,580 83
Colorado.....	\$ 441,235 82	2,605,681 60
California.....	231,870 84	16,167,484 05
Idaho.....	936,934 37	1,471,087 21
Kansas.....	29,417 00	4,031,602 00
Montana.....	22,477,045 75	4,031,602 00
Nevada.....	1,693,602 15	1,693,602 15
Oregon.....	130,175 31	221,262 14
Utah.....	320,107 09	320,107 09
Washington.....		
Wyoming.....		
Total.....	\$24,246,659 59	\$28,024,026 90

Mr. Valentine submitted the following as an approximately correct statement and estimate combined of the total yield of the precious metals for the States and Territories of the United States west of the Missouri river (except New Mexico):

Arizona shipments.....	\$ 163,739 93
Estimate like amount forwarded by other routes and conveyances.....	163,739 93
British Columbia shipments.....	1,349,580 83
Estimate 20 per cent. by other conveyances.....	3,046,917 32
Colorado—excessive if any variation.....	16,399,354 89
California.....	3,279,870 77
Idaho.....	2,408,001 53
Estimate 20 per cent. by other conveyances.....	481,600 31
Montana.....	4,030,929 00
Estimate 20 per cent. by other conveyances.....	819,153 80
Nevada, full.....	22,477,045 75
Oregon, full.....	1,693,602 15
Utah.....	327,437 95
Estimate ore and pig metal by weight.....	1,000,000 00
Washington, full.....	320,107 09
Total yield for 1871.....	\$58,284,029 66

The Mining Commissioner makes an estimate of the product which exceeds that of Wells, Fargo & Co. by \$8,378,971, a somewhat surprising difference. He thinks that Mr. Valentine's addition of twenty per cent. for under valuations and private shipments may be sufficient for California, but is far too little for Idaho and Montana. Mr. Valentine, however, said in his report that he was confident that the allowance of twenty per cent. was a liberal concession, and that the total product did not exceed \$58,284,029.66. Mr. Raymond, (the Mining Commissioner) does not understand why Mr. Valentine made no such allowance for Colorado, but left the impression by saying, "excessive if any variation," that the Colorado shipments were overvalued, and that the amount upon which express charges were paid exceed the total amount produced. The commissioner on the chapter on Colorado in his report gave the sum of \$4,663,000 as the total production of 1871, while Mr. Valentine only makes it \$3,046,917.32. Mr. Raymond says that the reason for this discrepancy is that Mr. Valentine entirely ignored \$923,000 shipped in mats, \$500,000 in ores and \$100,000 need by manufacturers. As Wells, Fargo & Co. gave no details this may be the case.

The Commissioner also considers the state-

ment with regard to Utah as imperfect, and thinks the estimate of the shipment of ores and base bullion at \$1,000,000 is a mere guess. He says the shipments of ore from Salt Lake City, in 1871, amounted to 10,806 tons, averaging at least \$150 per ton in silver, and the shipments of base bullion amounted to 2,378 tons, averaging \$175 per ton. According to this estimate it gives \$1,620,900 as the value of the ores, and \$316,150 as the value of the base bullion, to which Mr. Raymond thinks should be added \$500,000 for the lead contained in ores and bars. This makes Mr. Raymond's estimate of the bullion product of Utah, for 1871, about \$2,800,000, while Mr. Valentine's is only \$1,357,437.

The Commissioner thinks that the figures given in the table above for Arizona are too small, but cannot say precisely how much too small they are. His estimate of the gold and silver production of the United States for the year 1871, is as follows, compared with former years:

STATE OR TERRITORY.	1869.	1870.	1871.
Arizona.....	\$ 1,000,000	\$ 800,000	\$ 800,000
California.....	22,500,000	25,000,000	20,000,000
Colorado.....	7,000,000	3,075,000	4,663,000
Idaho.....	9,000,000	9,100,000	8,950,000
Montana.....	14,000,000	16,000,000	22,500,000
New Mexico.....	500,000	600,000	500,000
Oregon & Washon.....	3,000,000	3,000,000	2,500,000
Wyoming.....		100,000	100,000
Utah.....		1,500,000	2,300,000
Other sources.....	150,000	525,000	250,000
Total.....	\$61,500,000	\$66,000,000	\$66,663,000

—Including Wyoming. †Including Utah.

It will be noticed that the British Columbia shipments of \$1,349,580.83 are omitted from the Commissioner's table, and that Wells, Fargo & Co. omit the New Mexico product of

By comparing the figures given by the Commissioner, it will be seen that Arizona has fallen off in the yield since 1869 by \$200,000; California is \$5,000,000 behind 1870 and \$2,500,000 behind 1869; Colorado shows an increase of \$988,000 over 1870; Idaho has decreased her product \$1,000,000 since 1870 and \$2,000,000 since 1869; Montana falls short \$1,050,000 from 1870 and \$95,000 from 1869. The Nevada product, which was \$14,000,000 in 1869, \$16,000,000 in 1870 and \$22,500,000 in the year 1872, shows an increase over 1869 of \$8,500,000, and of \$6,500,000 over 1870. The New Mexican product remains the same. Oregon and Washington combined show a decrease of \$500,000 from both former years; Wyoming is the same as in 1870; Utah shows an increase of \$1,000,000. The "other sources" decrease \$275,000 from 1870, and \$250,000 in 1869, when Utah was included in the estimate.

It is evident from these figures that the placer mining districts have fallen off, while the quartz mining districts show a decided increase. The Commissioner says that the California mines have suffered from lack of water, and the reduced product is not to be taken as a measure of actual decline in these classes of mining.

The total increase in the bullion production of the United States, according to the Commissioner's tables,—which must be taken as authority on account of his official position,—amounts to only \$663,000 over 1870, but is \$5,163,000 over 1869. While it has materially fallen off in certain localities, it has materially increased in others—namely, Nevada and Utah. The nature of the increase shows clearly that the decline of production from superficial mining is more than compensated by a steady augmentation from deeper sources.

Fish Culture.

Nearly every known animal, large or small, has its own peculiar parasites or lice that prey

PARASITES WHICH ATTACK LARGE TROUT.

\$500,000, and the Wyoming product of \$100,000, as calculated by the Commissioner. To the "other sources" in the Commissioners' table he says he adds \$200,000 to cover the product of the Southern States, and the extraction of silver from lead ores not otherwise taken into calculation. He excludes, he says, from the statement, the product of the Wyandotte smelting works, Michigan, which is believed to amount to \$800,000, because the ores reduced there are obtained from Silver Islet, on the north coast of Lake Superior and outside of the United States.

Let us now see in detail where the difference lies between the Mining Commissioner's statistics and those of Wells, Fargo & Co., in which there is so great a discrepancy. The following table will show this plainly:

Com'r's Totals.	W.F. & Co.'s.	Difference.
Arizona.....	800,000	327,479.96
British Columbia.....	1,619,496.99	472,521
California.....	20,000,000	19,679,225.66
Colorado.....	4,663,000	3,046,917.32
Idaho.....	5,000,000	2,859,601.59
Montana.....	8,050,000	4,873,114.80
Nevada.....	23,500,000	22,477,045.75
Nebaska.....		22,955
Oregon & Washon.....	2,500,000	2,013,709.24
Utah.....	2,300,000	1,357,437.95
Wyoming.....	100,000	486,291
N.W. Mexico.....	500,000	424,663
Other sources.....	250,000	
Total.....	\$66,663,000	\$58,284,029.66

This table shows an apparent difference of \$9,148,474, but it really amounts to \$8,378,471, since Wells, Fargo & Co. took into account the product of British Columbia, which the Commissioner did not, as it is out of the United States; the Commissioner also has the sum of \$350,000 credited to Wyoming, New Mexico and "other sources," which Wells, Fargo & Co. do not give. The Commissioner does not separate the product of Oregon and Washington, as Wells, Fargo & Co. do, so their product is combined in the table.

The Two Great Mines of the Comstock.

The ore bodies of the Crown Point and Belcher mines, says the Virginia Enterprise, are without doubt the richest and most extensive ever developed in the mining experience of the world. The extent of the deposit—for it may be regarded as a single body—is of course unknown, but it has been estimated from assay and measurement that ore to the value of \$30,000,000 is now in sight in the two mines. The lowest estimate is \$20,000,000, and the highest \$40,000,000. These are enormous figures when we consider that the two mines are less than 1,700 feet in length; yet we find nothing extravagant in the highest estimate when we note the fact that over \$9,000,000 in gold and silver were taken from the two mines in 1872. Following is a comparative statement of the yield of the Comstock mines in 1871 and 1872. In 1871 the mines yielded as follows:

	Tons.	Value.
Belcher.....	18,747	\$1,198,920
Crown Point.....	59,949	1,370,884
Chollar-Potosi.....	68,635	2,233,383
Empire.....	8,701	123,616
Hale & Norcross.....	64,123	947,701
Savage.....	49,745	1,045,487
Sierra Nevada.....	18,294	147,117
Kentuck.....	9,183	140,069

Total.....287,377 \$7,804,093

Following is the yield for 1872, with the average value per ton of the product of the last quarter of the year:

	Tons.	Value.	Average.
Belcher.....	83,194	\$4,794,669	\$56 00
Crown Point.....	110,762	4,696,849	31 79
Chollar-Potosi.....	44,860	752,019	15 07
Empire.....	11,243	177,377	15 10
Hale & Norcross.....	38,064	617,325	17 64
Savage.....	63,083	811,867	14 03
Sierra Nevada.....	13,880	122,677	7 39
Woodville.....	660	10,604	16 16
Kentuck.....	11,183	141,847	8 90
Challenge.....	380	1,125	4 88
Total.....	371,349	\$12,028,152	

The average value of all the ore raised from the Comstock mine in 1871 was \$27, and in 1872 it was \$32; while the whole number of tons mined in 1872 was 83,972 in excess of 1871. These figures show that the ore bodies not only increase in volume, but in richness as well as in depth attained upon them, and give the Comstock mines the promise of a golden future. At present the Crown Point and Belcher are producing about three-fourths of all the bullion taken from the many mines of the Comstock; but prospecting is being vigorously prosecuted in the Ophir, Virginia Consolidated, Gould & Curry, Savage, Hale & Norcross, Chollar-Potosi, Imperial, Yellow Jacket, and many other mines of standing in the market, and important developments may be looked for before the close of the year. The most of these mines are still yielding more or less ore, as may be seen from the statements above given; but they are being steadily penetrated to greater depths in search of deposits in a measure corresponding with the vast ore bodies of the Crown Point and Belcher, and the faith is general with miners of experience that such deposits will in the end be found at many points between the Sierra Nevada and Overman.

Winnemucca Mines.

We gather the following items from the letter of a correspondent of the *Alta*: "Situated about half a mile from the railroad line is the thriving little city of New Winnemucca, containing about eight hundred inhabitants, not including a few scores of strolling Pioneers, and the usual complement of terrestrial Celestials. Immediately on the line of the railroad is the original, or 'Old Winnemucca,' upon whose outskirts the newly settled city is fast encroaching, and in a few years will grow into one incorporate body.

The City of Winnemucca

Is named from the river which commemorates the name of that old chieftain, whose glory as a warrior has long since departed, and whose once noble and brave warriors are now homeless wanderers throughout the barren valleys and mountain ranges, where, but a few years ago, he roamed in his wild and native majesty, fearing naught save the temporary influences of the advancing wave of civilization, which ever drives him westward toward the setting sun.

Mines and Mining.

There are sixteen mills in the county, only five of which are running, none using over ten stamps, and work ore by wet crushing, using principally the Stetefeldt and reverberatory furnaces. Within the last two years these mines have produced nearly \$1,000,000 worth of ore. Copper, lead, borax, salt, soda, etc., are also found in large quantities. In the

Battle Mountain District.

One of the most productive in the county, pure antimony is found in very large quantities. This ore is seldom found in a metallic state, and more seldom in its purity. It is a useful mineral, not only beneficial as an alloy in the reduction of other metals, but useful to the sciences and arts, to the medical profession, and was also used, it is said, in ancient times, by the ladies as a coloring to their eyes and cheeks. The word is derived from *anti-moachos*, or anti-monks—several having been poisoned by its indiscriminate use, at its early discovery; which, according to tradition, was in the latter part of the fifteenth century, by a German monk in the Prussian province of Saxony. These mines are said to be very numerous in the island of Bornoe, Sweden and the Hartz mountains, in France. A large vein has also been discovered in the Tulare valley, in Tulare county, and is said to be very productive."

Copper ore in large quantities and of extreme richness is said to have been discovered about 50 miles from Hamilton, in White Pine county.

GOOD HEALTH.

RESTLESS DISCONTENT.—Doctors are often called to prescribe for anomalous complaints whose leading characteristics are furred tongue, want of appetite, disturbed sleep, constipation, feeling heavy in the morning, moroseness, stuffy temper, restlessness and general unhappiness. This state provokes excessive consumption of tobacco and spirits in men; and in women, crossness to children and servants, and a dislike to seeing company.

These symptoms follow persistent abuses of the system. The remedy lies not in medicine, but in reformation. Let the patient ask himself about his eating, drinking, smoking, and other indulgencies. Let him consider, one by one, every drain upon his system. Then let him try a little less loading of the stomach, less strong chicory coffee, less tobacco, less drainage of every kind upon his nervous system. So sure as daylight follows darkness, there will become renovation of health and spirits without medicine.

There would come a great change in social life if we had moral doctors in the land. The excesses that poison our tempers, absorb us with frivolities and make trouble in social life, would be kept in bounds if every one had some fixed moral object to divert the mind from physical excesses, and from chronic ill-humor, which they always engender and transmit to offspring.

MANAGEMENT OF THE TEETH.—Tartar is an earthy deposit, which is made up of the solid constituents of the saliva, and accumulates around the necks and crowns of the teeth. The result of the deposit of tartar about the teeth is to cause the gums to be irritated, and then loosened from the teeth. When much tartar has collected about the teeth, it should be skillfully removed by a dentist, and only by a dentist, who will probably recommend some preparation of his own selection, to restore tone to the gums. The following is a good lotion, to be freely used after the removal of tartar, to strengthen the gums: Tannin, one scruple; brandy, half an ounce; camphor mixture, four ounces. To be used as a mouth wash, night and morning. In those in whom there is a disposition to the formation of tartar about the teeth it is only necessary for preventing its accumulation, to be very careful to cleanse the teeth thoroughly once a day, better still, twice, with a tooth-powder that is somewhat gritty; all the better is it if the gritty particles are soluble in water. The simple powders composed of chalk or cuttle-fish may be with advantage employed.

YELLOW SPECTACLES.—The use of yellow spectacles instead of green or blue is proposed by a recent writer, on the hypothesis that yellow is the ray having the least actinic or photographic power. This error has originated in a want of knowledge of the fact that, of all the rays, yellow has the most powerful action on carbon compounds. Since the eye in its construction involves the use of such compounds, it follows that the yellow ray of all others will have the strongest action on the eye. This agrees with our actual experience; for the yellow is by far the most powerful light to the eye, and the universal preference for green and blue glasses is owing to the fact that these, by shutting out the rays that act with the greatest energy on the carbon compounds of the retina, produce a milder and less irritating action on the organ when by disease or other cause its sensitiveness is increased.

PHYSIOLOGICAL EFFECTS OF COLD.—Recent investigations show that the effect of intense cold upon the human system is the result of changes which take place in the blood, consequent upon a very slight decrease of the general temperature. It has been found that not only a very slight elevation of the general temperature, if being continued produces changes in the blood, which must inevitably prove fatal, but that when the temperature of the blood is lowered only a degree or so below its normal state, equally fatal changes are produced, although of a different character. The blood seems to be in both instances devitalized, becomes incapable of rejecting its carbonic acid, and thus poison is carried through the system, producing the same narcotic effects that the inhalation of carbonic acid produces. These investigations have shown the fallacy of the belief that any animated being can survive after being wholly frozen.

COLD FEET.—Never go to bed with cold feet without applying a hot brick, hot bag of sand, a jug of hot water, or some warming material. Cold feet are often caused by tight shoes, stockings or garters. When the feet are habitually cold, a smart walk or run before retiring, will often make them comfortable for the night.

A POISONOUS PLANT.—A few years ago there was in the Royal Botanical Gardens at Kew, a specimen of probably the most poisonous plant ever introduced into England. It was the *Jatropha urens*, the properties of which arose so noxious that its possession is positively dangerous.

The ex-creator of the gardens was one day reaching over it, when its fine, bristling stings touched his wrist. The first sensation which he felt was a numbness and swelling of the lips; the action of the poison was on the heart, circulation was stopped, and he soon fell, unconscious; the last thing he remembered being cries of "run for the doctor." Either the doctor was skillful, or the dose of poison injected not quite, though nearly, enough to cause death; but afterwards the young gardener, in whose house the plant was placed, got it thrust into a corner, and would not come within arm's length of it. He watered the offender with a pot having an extremely long spout. In a short time, however, the plant disappeared altogether, and another specimen of the genus *Jatropha*, which was afterwards introduced, vanished in the like mysterious manner. It was presumed that the attendants were secretly determined that such plants should not be retained in the houses, to cause the possibility of an accident such as that which happened to their curator. *The Garden.*

EMOTIONAL EXCITEMENT MORE WASTING THAN INTELLECTUAL LABOR.—Serious and calm intellectual work is only very slowly destructive to the nervous health, while emotion, unless directed into proper channels, is highly destructive to the nervous system. The conventional ideas as to the propriety and utility of certain kinds of emotional excitement do visibly bear, in the experience of medical men, the very worst fruit possible. It is true that the emotion of repentance for real guilt is not a thing to be shunned; but the habit of self-torturing introspection, which the clergy are especially earnest in recommending as a means of spiritual purification, is so far from promoting the existence of a really high and pure standard of ethics, that it ruins both body and soul, in the majority of cases, wherever it is applied on a large scale. More especially the habit of inducing unnecessary emotional excitement in young persons who are just entering the dangerous period of commencing sexual life is so morally and physically injurious to a large number of individuals, that it may well be questioned whether those individuals might not have been more safely left in total neglect and ignorance.—*Popular Science Monthly.*

THE INEVITABLES OF MORAL LIFE.—Diseases of the kidneys, liver and brain, for which physicians formerly bled and purged with great hopes of success, we now regard as cases of disorganization, which afford no ground of hope. Nor in the utmost improvement of our therapeutics can we ever expect to find a cure for all the morbid conditions which may be revealed by pathology. A boundary has been set to the operations of the human body. Its machinery must wear out and run down. Age obstructs and deranges its organization. The days of our lives have been limited to three score years and ten, and though by reason of uncommon vigor they may be occasionally extended beyond four score years, still, from the very nature of the frame, it must at last experience decay; and alchemy there is none, by which it can recover its healthful action.

CAUSE OF SCURVY.—M. Leven, being in charge of one of the hospitals of Paris during the siege, made a study of scurvy, and concludes that it is not produced by a want of vegetables, nor are vegetables indispensable for its cure, but that it is the result of bad hygienic conditions in those who contract it. Cold, dampness, excessive work, moral depression and insufficient alimentation, he thinks are the principal causes of scurvy. He believes it to be a fatty degeneration of muscular system, beginning in the heart, and those muscles which are most active, when the degeneration appears in the liver, kidneys and their organs. A great number of cures were obtained by the use of raw meat without vegetables.

MENTAL VIGOR IN OLD AGE.—It is related of Arnauld, the Jansenist, that he wished his friend Nicole to assist him in a new work. Nicole replied: "We are now old; is it not time to rest?" "Rest," exclaimed Arnauld, "have we not all eternity to rest in?" Dr. Samuel Miller says: "There is no doubt that the premature dotage of many distinguished men has arisen from their ceasing, in advanced life, to exert their faculties, under the impression that they were too old to engage in any new enterprise of industry."

BOYS USING TOBACCO.—A strong and sensible writer says a good sharp thing, and a true one too, for boys who use tobacco: "It has utterly spoiled and utterly ruined thousands of boys. It tends to the softening and weakening of the bones, and it greatly injures the brain, the spinal marrow, and the whole nervous fluid. A boy who smokes early and frequently, or in any way uses large quantities of tobacco, is never known to make a man of much energy, and generally lacks muscular and physical as well as mental power. We would particularly warn boys who want to be anything in the world to abstain tobacco as a most baneful poison."—*Exchange.*

USEFUL INFORMATION.

INTERESTING DISCOVERY.—CAN THE CRAWFISH REPRODUCE EYES?—A curious discovery has just been made by a savant here, writes the Paris correspondent of the *Pall Mall Gazette*, though there is some doubt as to the benefit which either humanity or the crustaceous fish operated upon will derive from it. Mr. Chantry has long been engaged in studying the natural history and physiology of the crawfish, and from a paper just read out before the Academy of Sciences, it seems that this careful observer has found out that when young crawfish are deprived of their eyes, new ones will grow in the interval between the shedding of two shells, and this is a perfectly normal fashion. But when adults are operated upon, the regeneration of the eye is slower and more irregular; and not only is the organ generally deformed, but two eyes often take the place of one.

HOW TO CLEAN PAINT.—A chemical journal gives the following advice: Use but little water at a time; keep it warm and clean by changing often. A flannel cloth is better than cotton. Be careful of soap. Put but a little soap or skim-milk in the water; add soap to the cloth when needed. A sharp piece of soft wood is indispensable for the corners, the point will become like a paint brush. A saucer of sifted ashes, used where the paint is badly smoked or fly-specks are thick, is better than soap; wipe last with clean wet towel, and don't spill a drop of water. Never put soap on glass unless it can be well rinsed, which can never be the case with windows; wash off dirt in clean warm water and dry; then, with a paste of whiting and water, and with a cloth, place a little in the center of each pane. With another cloth rinse over the glass; next rub off with a dry cloth till the window shines like crystal.

SEPARATION OF BRASS AND IRON TURNINGS.—The following item is from the *Berlin Industrie Blatter*. We do not know their source of information, but from the character of the publication, suppose it to be trustworthy. "In order to separate such filings it has been customary to draw a magnet by hand through the mass, thus taking out the iron and steel while leaving the brass. Recently a very suitable machine appeared for saving this tedious hand labor, invented by a French Engineer named Bavin, in the machine works of Cail & Co., Paris. Now, however, Mr. Webb employed in the splendid works of the London and Northwestern Railway, at Crewe, had reached the desired end by a very simple and economical process of smelting.

The mixed iron and brass turnings and brass slag are mixed with limestone, coal-dust, and oxide of iron or iron scales, and smelted; the brass settles through the fluid slag to the bottom and is run off into ingot mold."

SEASONING WOOD.—A writer in an English journal informs us that a small piece non-resinous wood can be seasoned perfectly by boiling four or five hours, the process taking the sap out of the wood, which shrinks nearly one-tenth in the operation. The same writer states that trees felled in full leaf in June or July, and allowed to lie until every leaf has fallen, will then be nearly dry, as the leaves will not drop off themselves until they have drawn up and exhausted nearly all the sap of the tree. The time required is from a month to six weeks, according to the dryness or wetness of the weather. The floor of a mill laid with poplar so treated and cut up, and put in place in less than a month after the leaves fell, has never shown the slightest shrinkage.

LOSS OF HEAT IN COOKING, ETC.—It has been computed that, in common domestic fires, seven-eighths and even more of the heat capable of being evolved from the coal pass up the chimney unutilized, so far as mere warming is concerned. About half of the heat generated by the fire is supposed to be carried off with the smoke, about one-fourth in the constant current of the warmed air of the room into the chimney between the mantel-piece and the fire, and the remainder of the loss of heat is represented by the unburned particles of carbonaceous matter in the smoke.

WHOLESALE BURNING OF GAS.—One of the gasometers of Manchester, England, was recently discovered to have a large burning jet issuing therefrom. All efforts to extinguish the flame were ineffectual, until the entire contents of the gasometer 600,000 feet of gas, were consumed. Many residents in the immediate vicinity made hasty removals, fearing an explosion, but none occurred. Nothing is known as to the cause of the opening by which the gas escaped or the origin of the fire. The occurrence was one of a very singular nature.

A SUMMER BOOT.—The bottoming of the boot for summer should be of medium thickness, but if any, rather thicker than thinner, so that the surface of the sole of the foot may be thoroughly protected from the ground and stones. The disadvantage of a thin sole is that it produces callosities at the bottom of the foot, at the parts corresponding to the bones where they are formed.

THE STORM SIGNAL SYSTEM has been reduced to such a nice point in England, that when the storm ball is run up at Greenwich, it is telegraphed to every part in the kingdom. Any vessel that leaves the port after the ball is up forfeits its insurance.

DOMESTIC ECONOMY

Baked Beans.

White beans may be considered one of the substantial dishes. When properly cooked, they are wholesome to a stomach of normal strength, if the taker be accustomed to active exercise. They are not so good for the sedentary, but the greatest difficulty in digesting them results from the fat usually cooked into them. They may not relish quite so well without this at first, but proper cooking will help greatly, for they are much richer if cooked in but one water and that not drained off. The very water that is called strong, and thrown away when the beans are half done, would, if cooked make a toothsome soup. Let it remain, having the beans nearly full of the liquid, and salt just before serving. They should cook gently but thoroughly, being kept covered, so as not to lose the flavor. The time required depends much on the age and variety of the beans. Some will cook in an hour and a half, while others will require three hours. They are best very tender, beginning to fall to pieces, but not so soft as to become thick and pasty with the necessary handling. Some prefer them thick; but in that case they seem to require some trimming—while, if more moist, they become a trimming to other dishes, especially to the potatoes eaten with them. Indeed, it makes a very palatable dish to cook the potatoes with the beans, being careful to serve them as soon as the potatoes are done. A more stylish dish in appearance, but no more palatable, is made by placing the beans, when nearly done, in a nappy (in which they can be served,) covering, the surface neatly with potatoes pared and halved, and baking until the latter are done. Some like a squeeze or two of lemon over them on the plate, and to most tastes they serve well with rather acid fruits, like cranberries or sour baked apples, or with cold or warm slaw, while sweet potatoes and rye-and-Indian bread form an agreeable contrast.

Bean soup is a dish that many people, and especially children, would relish if properly made. It requires about half a pint of cooked beans for a quart of soup. Mash and boil until well diffused in the water, and then run through a colander to take out the skins. Thicken with about one gill of wheat meal, and add a sprig of thyme if desired. Boil five minutes and salt to the taste.—*Science of Health.*

Warm Plates for the Table.

Warm plates are most satisfactory adjuncts to the breakfast and dinner table, for without them all articles of food will cool rapidly; and during this last cold snap a cold plate would have quickly transformed sausage, steak, fried potatoes and buckwheat cakes into decidedly "cold victuals," and frequently the difference between a good dinner and a poor one depends upon a warm or a cold plate. And in no case are they so useful as when mutton is served, for its fat melts only at a high temperature, and quickly becomes congealed upon a cold plate, making it very repulsive excepting to a Greenland or Esquimaux.

Now, it is a very easy matter to warm the plates, if a little attention is paid to them, and when the breakfast table is laid the night previously, the plates can be placed in the tin oven at the back of the stove, or on the oven connected with the range—or if neither of these places are come-at-able, they can be put inside of the stove oven, as that is an article which every house is supposed to possess. After they have become warm enough, they should be put into a cooler place, but not so cool that they will lose too much heat.

The furnishing stores offer very handsome plate-warmers, made of Japanned ware, and also racks of galvanized iron wire, which can be placed upon the stove, or over a hot air register. When plates require to be warmed in haste, they can be dipped into boiling water, and then wiped off.—*Country Guest.*

Economical Cookery.

In all departments of housekeeping it costs less to be neat, orderly and systematic, and to know just how much butter, sugar, eggs and flour to use on baking day, as well as just how long to boil or roast a piece, tender piece of meat, that it may not be toughened, and its sweetness and nourishment cooked away.

Goodhousekeeping is a science, and a science, of which an unpracticed hand is entirely ignorant. Experienced cooks make delicious and inexpensive dishes of odds and ends left over from meal to meal, which in most housekeepers are more or less wasted. Who would believe that the well picked bones of a roasted chicken, with two or three little beef bones taken from the roasted beefsteak which has served at breakfast, boiled two hours in about a quart of water, will make excellent soup good for the sick and tempting to the most delicate taste? Try it and see.

Soup is strengthening, and can be made much cheaper than most people imagine. Beef bones are just as good for soup after they have been roasted as any, and save much expense.

There is no accomplishment for which a woman has so much reason to congratulate herself and be proud, as for being a good housekeeper, and the foundation of housekeeping is to be a good cook.—*American Farmer.*

MINING SCIENTIFIC PRESS

B. EWER.....SENIOR EDITOR

DEWEY & CO., Publishers.

Table of Contents.

GENERAL EDITORIALS.—Bullion Product of 1872, 182. Appliances and Methods of Roasting Ores; Worked Out Mineral Lands, 184. Cosmic Forces; Academy of Sciences, 185. **ILLUSTRATIONS.**—Warren's Aero Steam System, 177. Trout Parasites, 182. James L. Plympton; Turnbridge's Amalgamator, 185.

CORRESPONDENCE.—Utilization of Placer Tailings; The American Fire Detector; Affaire in Eureka; Letter from Julian District, 178.

SCIENTIFIC PROGRESS.—Is Heat any Mode of Motion of the Atoms of Ordinary Matter; Water on the Moon; Vibrating Motion; Still Another Asteroid; Biela's Comet, 179.

MECHANICAL PROGRESS.—Joining Band Saw Blades; Improved Blast Furnace; The Preservation of Exposed Sheet Iron; To Remove Fat from the Water of Condensed Steam; Cutting Tools of Copper; Prize for Steel; A New Fuel for Warming Cars; Repeating Oxidation, 179.

GOOD HEALTH.—Restless Discontent; Management of the Teeth; Yellow Spectacles; Physiological Effects of Cold; A Poisonous Plant; Emotional Excitement More Wasting than Intellectual Labor; The Inevitables of Moral Life; Cause of Scurvy; Mental Vigor in Old Age; Boys Using Tobacco, 183.

USEFUL INFORMATION.—Increasing Discovery.—Can the Crawfish Reproduce Eyes; How to Clean Paint; Separation of Brass and Iron Turnings; Seasoning Wood; Loss of Heat in Cooling, Etc.; A Summer Boot, 183.

DOMESTIC ECONOMY.—Baked Beans; Warm Plates for the Table; Economical Cookery, 183.

MISCELLANEOUS.—Mount Diablo Coal Mines; Exploration of Africa; Marshall's Sale of Mines; Another New Mining Company Proposed; A Hoax; New Coal Mines; Duty on Iron Pipes, 178. The Fairfield Mine; Bullion Product of 1871; The Two Great Mines of the Comstock; Winnemucca Mines, 182. Decision in Regard to Swamp Land in California; The Oxy-Hydrogen Furnace; An Expected Strike; English Railroad Iron; The Virtue Mine; The Limestone Belt of California; Forest Culture, 186.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notice of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 180.

MINING SUMMARY from various counties in California and Montana, 165.

SAN JOSE RAILROAD.—The *Call* has information that Thomas A. Scott will shortly assume control of the San José Railroad. That paper says that it is now supposed that the purpose of Scott is to construct the Texas and Pacific Railroad so as to enter California near the thirty-fifth parallel, with the main lines coming to San Francisco via the Coast route, and that a branch line will extend to San Diego.

VIENNA EXPOSITION.—A dispatch from New York states that notwithstanding the difficulties thrown in the way of Commissioner Thomas B. Van Buren, owing to the European Patent laws, and by Congress in limiting the appropriation to a small sum, the United States is certain of making a creditable show at the Vienna World's Fair, that opens May 12th.

THE WHITE PINE people are talking about establishing a bank of their own, the branch of the Bank of California having been closed. The place is beginning to show signs of more activity and several of the mills will resume operations shortly.

PHOENIX.—According to the *Eureka Sentinel*, the Phoenix Silver Mining Company offers to its creditors forty cents on the dollar, or notes at six months, otherwise the company will go into bankruptcy.

DOO TRAINS are being used in transporting provisions from Alta City, Little Cottonwood, Utah, to the neighboring mines.

THE CALIFORNIA BORAX COMPANY, whose mine is located seven miles north of Lower Lake, on Big Borax Lake, resumed work last week.

THE HORSE DISEASE is hindering operations at the Owens river mines. It has made its appearance at Amazon also.

Appliances and Methods of Roasting Ores.

The recent lecture by Eugene N. Riotté before the Polytechnic class on the subject of roasting was a very interesting one and we regret we cannot give it in full. A synopsis will, however, amply repay perusal. The lecturer commenced by saying that this process of roasting was the fundamental process by which ores and metallurgical products are prepared for beneficiation and of course the latter can not give the desired results if the roasting has not been properly performed. Roasting in the mildest sense of the term means to effect a chemical change by the application of heat without smelting.

Oxidizing Roasting.

If the ores to be heated contain combinations of sulphur, antimony and arsenic and we intend to oxidize these metals and obtain them either as oxides or in part as sulphates, we call this oxidizing roasting. Such, for instance, is the case in the roasting of gold-bearing pyrites of iron, preparatory to the extraction of gold by Plattner's process, with chlorine gas. Here we want the iron completely changed to peroxide, so the presence of a sulphuret or sulphate would be injurious to the result of the chlorination process. As an example, when we want a part of the metals left as a sulphate, Mr. Riotté mentioned the roasting of silver-bearing copper matte in Mansfield. The matte is subjected to careful oxidizing roasting, and the metals are left as oxides, except the silver and a small part of the copper which, at the end of the operation are in the form of sulphates and subsequently leached in hot water. This process is executed with such exactness that only about one per cent. of the silver is lost.

Reducing Roasting.

Sometimes it is desirable to reduce certain metallic salts, namely: Sulphates, antimonates and arsenates, which have been formed during oxidizing roasting, and change them as much as possible into oxides. This is done by mixing finely pulverized coal with the charge by which the sulphuric acid is reduced to sulphurous acid and the arsenates to metallic arsenic, which is volatilized. This we call reducing roasting. This method is used, for instance, in roasting copper ores containing arsenic and antimony in order to remove these impurities.

Chloridizing Roasting.

If it is necessary, on account of the following modes of extraction, to change certain metals into chlorides by roasting with the addition of salt, we have a chloridizing roasting; an instance is the roasting of silver ores for amalgamation or lavification.

Volatilizing Roasting.

In some cases it is necessary to drive off certain substances, as hydrates water, sulphuric acid or carbonic acid, quicksilver, etc., which we speak of as volatilizing roasting. This is done, for instance, where carbonates of iron are prepared for reduction in a blast furnace by roasting in shaft furnaces.

Heap and Kiln Roasting.

The oldest and simplest mode of roasting is roasting in heaps. Here sulphuret ore or matte is piled in pieces on a bed of fuel which ignites the sulphurets. Of course this method can only be used where a partial roasting is required. This is very often the case when sulphuret ore or matte is prepared for smelting and the object in view is to collect certain metals (mainly copper) in a matte, and dissolve others, as iron, as oxides in the slag, or to concentrate the matte.

In many metallurgical works it is found advantageous to manufacture sulphuric acid from the sulphurous acid which is formed in roasting. In this case the ore is roasted in kilns, from which the acid fumes are conducted to the lead chambers. From this kiln there is only one step to the

Hearth and Shaft Furnaces.

Roasting in these furnaces is effected in two ways. Either the ore and fuel are charged in layers or the furnace is heated by fire-places. The process is more complicated where pulverized ores are to be treated, and exact results have to be obtained as to certain chemical changes, upon which the operation depends. The hearth roasting furnaces were, until recently, the only ones in use, with their innumerable modifications. The heating of the charge is either effected directly by the flames from the fire-place, (reverberatory furnace) or it is effected by heating the hearth and arch from the outside (muffle furnaces).

The latter form is used when the gaseous and volatile products of roasting are to be utilized, as in the instance of roasting sulphurets for the manufacture of sulphuric acid. Another instance of the use of the muffle furnace is in the roasting of arsenical pyrites to obtain arsenious acid. Sometimes the muffle and reverberatory furnaces are combined and the bottom of the muffle forms the arch of the reverberatory furnace.

Roasting on Hearth Furnaces.

From the construction of furnaces it follows that roasting requires time, labor and skill. In order to roast a considerable amount of ore in a reverberatory furnace the charge must be spread several inches high; consequently it takes not only time to bring it to a roasting point, but considerable stirring is necessary to bring the particles to the surface. Another disadvantage in this construction of this furnace is that the ore near the first bridge is exposed to a higher heat than that near the flue. In order to insure uniform roasting it is necessary to shift the charge several times. Great care and judgment is required in regulating the heat. If the heat is too high in the beginning the ore even melts and forms lumps which are difficult to destroy, and are imperfectly roasted at the end of the operation.

Parker's Furnace.

The first attempt to do away with the manual labor of stirring was made about 20 years ago by Parker, in England, who constructed a circular reverberatory furnace with horizontal iron stirrers, fastened to a vertical revolving shaft. These furnaces, however, have not been generally introduced for the reason that the machinery not only gets out of order, but the roasting itself is not so perfect as desired.

Gerstenhofer's Furnace.

It was left to Gerstenhofer about seven years ago to invent a roasting furnace, the construction of which was based on an entirely new principle. In Freiberg, the smelting works received quantities of concentrated sulphurets of iron, small amounts of silver and copper more or less finely pulverized. There being difficulties in this way of roasting these in either kiln or muffle furnaces to make sulphuric acid, Gerstenhofer devised a furnace for treating them in which is based on the principle of free fall, and which was soon introduced in the principal metallurgical works in England and on the Continent. It was, however, soon found to be available only within narrow limits. The roasted ore stuck on the terraces, fell down in layers and obstructed the furnace. This is also the case when roasting with salt is attempted. It was also found that when complete desulphurization was essential the furnace was not satisfactory, for reasons not difficult to discover. To accomplish a perfect roasting, the roasted ore must be exposed at the end of the process to a high heat. To do this by adding fire-places to the furnace was found impracticable. The conditions therefore, under which the Gerstenhofer furnace can be used are as follows: First, the substances to be roasted must carry sufficient sulphur to generate a roasting heat; second, the roasted ore must have no tendency to "sinter;" third, it must not be required that the charge should be perfectly desulphurized. This furnace is mainly used to roast pyrites of iron and copper ore and matte, in making sulphuric acid when perfect roasting is not required.

As the subject of cheap roasting is an important one in our mining regions, it is no wonder that innumerable mechanical roasting furnaces have been brought before the public. Leaving out all those which are based upon entirely theoretical ideas and have never accomplished any practical results, we may classify all efforts in this direction under two heads, viz: cylinder and shaft furnaces. Of the former it is only

Bruckner's Furnace

Which has accomplished good results and is of practical value. This furnace is not continuous working. All ores which have a tendency to "sinter" must be excluded from the furnace; in other cases I can recommend it heartily for works of small capacity, all other furnaces which are continuous working give unsatisfactory results where complete desulphurization or a thorough chlorination is required. The ore passes through the cylinder too quickly, is not sufficiently exposed to oxidizing influences and in most cases is discharged in layers containing imperfectly roasted ore inside. Of the shaft furnaces we must mention the

Whelpley & Storer and Keith Furnaces.

Those who understand the principles of roasting will understand at once by seeing this furnace that the construction is based upon a false principle. The ore enters the furnace where it is hottest and drops where it is coldest. For good roasting it is essential that the temperature at the beginning should be low and at the end high. In this furnace the ore remains too short a time the fall being accelerated by the downward direction of the draft. The Keith furnace is liable to the same objection. This latter furnace was introduced about nine years ago in Colorado for roasting gold-bearing sulphurets.

The Stetefeldt Furnace.

While residing in Austin the chloridizing-roasting of silver ore attracted Stetefeldt's special attention and he became convinced that the old reverberatory furnaces would be superseded by a cheaper and more perfect mode of roasting; he found by a few experiments that silver ores could be chloridized with the best results if a mixture of ore and salt were allowed

to drop through a shaft, heated by fire-places near the bottom, against the rising current of hot gases. Here all the conditions for a good roasting are given. The ore enters the shaft where the heat is lowest, which heat increases as the ore falls. The gases formed by the roasting, sulphurous acid, hydrochloric acid, chlorine and volatile chlorides, surround every particle of the ore and materially effect its desulphurization and chlorination. This upward motion of the draft prevents the ore from falling too fast. At the same time the heat is utilized better than in any other furnace. As the draft in the shaft is very strong the finest portions of the ore do not drop down the shaft but escapes unroasted in the rising gases through the flues. To roast the dust a fire-place is constructed in connection with the flue. The speaker here described the Stetefeldt furnaces and spoke of its general use.

A number of other furnaces for chloridizing-roasting which have been brought before the public are but mere modifications of the Gerstenhofer, Whelpley & Storer or the Stetefeldt.

The lecturer closed by considering the chemical changes which took place in chloridizing-roasting, those cases where ores have to be roasted before amalgamating, and stated that although he had been asked to deliver a lecture on metallurgy and local adaptation of roasting and smelting furnaces, he had come to the conclusion that it was impossible to concentrate so much matter into one lecture, without treating the subject superficially.

Worked Out Mineral Lands.

An important decision to both the mineral and agricultural interests has just been made by the Secretary of the Interior in relation to mineral lands. On the 13th inst. the Secretary of the Interior decided the case of Iohabod Dickinson against John Harrington, involving the title to lands in Calaveras county, California. Secretary Delano reversed the decision of Commissioners Drummond, and decided that although the lands had been heretofore used for mining purposes, they are now worked out, and no longer mineral, but must be considered agricultural lands.

In view of this decision the remarks of our correspondent on another page, in this issue, on the "Utilization of Placer Tailings," are particularly applicable. He says the soil made by the tailings from these placer grounds is very productive, except in cases of large hydraulic claims. His suggestions, with regard to utilizing the ground, are well worth attention. Placer miners now who abandon their ground must be careful to take necessary precautions, if their absence is only temporary, that the ground is not taken up as agricultural. This decision will bring to an end the carping of a certain class who inveigh against the country being cut up by surface mining operations. In many instances the ground is benefited for the purposes of agriculturists, as the large flats can be utilized, and, in fact, the soil is really better than it was in the first instance, being deep and rather porous.

In this connection it may be stated that the tailings from quartz mills, if in situations where the land can be periodically flooded may be utilized in the culture of the cranberry. The silicious soil thus formed is admirably adapted for this purpose, and as the quartz tailings are nothing more than pure sand, the cranberry can be grown upon it to advantage. Thus we see that, as well as furnishing the money for the "sinews of war" as well as peace, the miner in his work prepares a place for the farmer to glean his profit, making the ground yield up its treasures in both instances. Some of our mill men might take a hint from this, and where the mill is near a river, and circumstances are favorable, they can follow the vocation of both miner and farmer to advantage. In fact we are sure that in some particular cases, where the mill managers are in the interest of rings rather than stockholders, that the stockholders might make more money out of an acre of tailings, planted with cranberries, than they could out of a \$100,000 quartz mill with a \$1,000,000 mine.

Work at the Bellingham Bay coal mines is progressing favorably. There are at the present time over 3,000 tons of coal in the chutes ready for shipment.

QUICKSILVER has been found about two miles from Calistoga, Napa county, on the farm of J. Schram.

COAL has been discovered on the line of the Union Pacific Railroad, within 20 miles of Ogden.

CANON CITY, a mining camp in Grant County, Oregon, claims to ship \$300,000 in gold yearly.

Repulsion as a Cosmic Force.

The nature and action of repulsion, as a cosmic force, does not seem to have heretofore received that consideration which appears to be due to the numerous and important phenomena connected with it. Such philosophers as Bosovich, Robert Hooke, Bessel and even Sir Isaac Newton have, indeed, referred in terms more or less unmistakable, to their suspicions that "molecular repulsion"—a force the knowledge of the existence of which is as old as the most ancient Greek philosophy—exerted a wide and important influence in the cosmical economy of the universe, approaching in its universality to the force of gravitation. But it is only quite recently that the theory of its existence as a cosmic force has been carefully discussed at any considerable length.

Dr. Charles Winslow, of Philadelphia (we believe), has had the boldness to enter this field of enquiry, and call attention to certain facts and phenomena of great importance as bearing direct and (as he thinks) unequivocal testimony to the existence of this force, as a counterpart to gravitation. The Doctor carefully traces it into its broadest expansions, applications and connections with other forces and all forms of matter. He holds that repulsion is a general and cosmic force, cognate in origin, equal in value, quantity and extent with the force of gravitation, going hand in hand, inseparably with gravitation, into atoms and masses throughout space, even into the dynamics of celestial motion; and that it plays an equal part with attraction, as a primary agent in the production of all physical, organic and vital phenomena.

He holds that molecules are endowed with two positive and inseparable forces—attraction and repulsion. That a principle of duality or antithesis exists between these two forces, similar to that which exists between positive and negative electricity. The Doctor has recently published an elaborate work upon the subject, forming a volume of some 500 pages.

The progress of knowledge upon abstract subjects has always been slow. It is true we have positive knowledge of much; but how infinitely much more remains to be learned! Dr. W., in the introduction to his book, very truthfully remarks that every close thinker has often perceived that with the advancement of experimental discovery and solid knowledge, physical theories grow perplexing on account of the insufficient development of fundamental principles. That investigators in many fields of research feel oppressively hemmed in by some inexplicable deficiency of means to final inductive analysis. We are now, more than ever before, living in an investigating age; and although in positive science nothing can be assumed, still the path of solid progress can seldom be successfully trod without the frequent assumption of hypothesis, as a means to that end.

The Doctor is quite modest in his assumptions, and like an earnest investigator is free to acknowledge that he considers his work as one only just commenced, and that his theory will not be accepted as science without much further and more careful consideration. His aim, thus far, has simply been to set forth the subject in its broadest aspects, so as to invite to its consideration the attention of the learned, hoping that those who come after him may make more solid the ground and more sure the steps where he has reached only uncertain results or failed altogether.

In this connection we would call attention to an article on page 179 of this issue, in reference to the kind of motion involved in the phenomena of heat. Do we not need something more than is usually understood by "molecular repulsion" to substantiate the doctrine that heat is a mode of motion?

NITRO-GLYCERINE.—We notice that the Supreme Mining Bureau in Breslau, Prussia, has issued regulations concerning the use of blasting materials containing nitro-glycerine, in which the use of pure nitro-glycerine is strictly forbidden. Only mine owners or their commissaries are allowed to purchase dynamite or other nitro-glycerine preparations, and then only in the form of cartridges, and of dealers commissioned by the government. It must be kept at the mines at least 150 meters from the nearest tramways or shafts. Instructions are given about transportation, and trestling the frozen cartridges. The caps must not be kept near the cartridges and all vessels which have contained any of the nitro-glycerine preparations must be immediately burned in an open fire.

Tunbridge's Amalgamator.

For some time past we have seen a paragraph going the rounds of the press, to the effect that one John Tunbridge, of Newark, New Jersey, had recently invented a process for amalgamation which was particularly simple and cheap. It seemed rather strange that any one in that State should invent a process which is applicable only to mining localities, but supposed, of course, that it would eventually find its way to this Coast, which it has done, and Wiester & Co., No. 17 New Montgomery street, have the patent right for sale. We have obtained from them a drawing from which the accompanying cut was made.

The engraving represents a vertical section of the apparatus. *A*, and *C*, are two vessels connected by a pipe *b*, and provided with screens *f*, *f*, at different altitudes. *B*, is the ore or pulp pipe, and *a*, its check valve connecting with a vertical discharge pipe *d*, having a cock *e*. The vessel *A*, is filled as far as the pipe *b*, or nearly so, with quicksilver, while balls of copper amalgam, or copper balls coated with quicksilver are placed upon sieves in the chamber *C*.

The mode of operation is as follows: Power is employed in connection with the pipe *B*, to force the ore washings through the pipe, the valve *a*, opening inward and yielding to any force exerted through said pipe. The washings then pass up through the quicksilver in the chamber or vessel *A*, and are subdivided in passing through the screens *f*, *f*; they are then

AMALGAMATING APPARATUS.

forced through the tube *b*, into the other chamber *C*, pass down among the amalgam balls and screens and are discharged through the pipe *c*. The effect produced on the pulp is to abstract the principal part of the metal in Chamber *A*, and the greater part of the residue while passing through the amalgam balls in the chamber *C*.

The machine, which was put up in the East, had, as the cut shows, two receptacles, eight inches in diameter by two feet high. The perforated disks placed across the chambers were made of copper. One foot of mercury was poured into the chamber. In this bottom is an inch and a half iron tube, fifteen feet long. The "process" consists in letting on the steam containing the pulp or fine gravel at the top of this tube. Although the patentee claims the use of power to effect his object, the pulp or gravel, by its own hydraulic pressure and without any other power passes up through this foot of mercury, and passes off through the pipe *b*, into the other receptacle *C*, where it comes in contact with the copper balls on the disks *f*, and thence through the discharge pipe *c*. The perforated disks placed at short intervals across the chambers cause the sand or pulp to break up finely, and present, at some portion of its passage, every particle of the precious metals to the action of the quicksilver.

This system can of course only be practical or useful with free gold, but possesses an advantage in bringing every particle of gold in direct contact with the quicksilver. Fine float gold would be caught in this case unless in such a chemical or greasy condition that it would not amalgamate at all. Perhaps a large machine of this patent could be made to work well with tailings in favorable positions, as the process is continuous and the quicksilver would only have to be removed in case of a clean-up. The inventor thinks it is especially applicable in placer mining. Where it could be placed properly it might be used to advantage at a mill, where the tailings could be passed through

these chambers after having gone through the pans, settlers, etc. If there was any saving at all it would count up, since the apparatus is extremely simple and is automatic, requiring little attention. If any one of our readers make any experiments with this device we hope they will inform us of its practical working for the benefit of the mining public.

The Inventor of the Plympton Skate.

The subject of the accompanying cut, Jas. L. Plympton, is one whose name is well-known to all lovers of roller-skating, as the man through whose inventive genius that amusement has been brought to the position it occupies. Mr. Plympton was born in Medfield, Mass., in 1828. He developed a mechanical turn of mind at a very early age, and at 16 years commenced work in a machine-shop at Walpole in his native State. A few years afterwards he was appointed foreman in a large shop in Claremont, N. H., at which time he first became interested in patents and patent law. When 21 years old he associated himself with his brother in machine building in Westfield, Mass., and the firm of H. R. and J. L. Plympton, now well known as designers, manufac-

JAMES L. PLYMPTON.

turers and dealers in furniture, etc., was formed.

Their success in Westfield was very rapid, because both brothers enjoyed good faculties in business enterprise, and built up an enduring reputation for fair dealing with all—from the lowest workmen in their shop to the heaviest tradesmen with whom they had to do. Our personal business relations with Mr. Plympton at Westfield are among our pleasant recollections. Afterwards the firm moved to New York and are now carrying on a large trade, in the above-named business, with a branch establishment in Boston.

Having improved his health from a season of ice-skating at Central Park in 1862, it was his desire to continue the exercise. Artificial ice having proven a failure and no roller-skate being made upon which the curved movements of ice-skating could be performed, he turned his attention to inventing one and soon produced a roller skate, which could be guided by the natural inclination of the wearer. The *Plympton Skate Roll*, a lively little monthly published at Woodward's Gardens in this city, (the head centre of skating on the Coast) and devoted to the interests of the skating community, from which we gain this information, says that from this simple instrument, he has reared one of the most popular and beneficial systems of exercise extant, and of which it has been justly said "As Howe's sewing machine is to our industrial wants, or Morse's telegraph to commercial pursuits," so Plympton's system of exercise is to the social and physical wants of society.

Having completed the necessary mechanical appliances, he formed a company in 1863 called the New York Roller Skating Company, which is still flourishing under the supervision of its founder. He has succeeded in amassing a considerable fortune from this invention. Mr. Plympton is an unusually ingenious man and has peculiar ways of his own. As an instance of this may be cited the fact that his marriage ceremony was performed on an express train going 30 miles an hour, probably the first one to do that sort of thing. As a more constant interest in roller skating is kept up in California than elsewhere, it is hoped that this gentle-

man will yet pay us a visit, and receive as he certainly would, a warm welcome from the admirers of modest geniuses generally, and enthusiastic skaters in particular.

PATENTS & INVENTIONS.

Telegraphic List of U. S. Patents Issued to Pacific Coast Inventors.

(REPORTER OFFICIALLY FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch, Dated Washington, D. C. March 18th, 1873.

FOR WEEK ENDING MARCH 4th, 1873.

SOLLETRINO TOOL.—Lewis Cutting, S. F., Cal. MERICATED TOWEL.—Lydia Stewart, S. F., Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

Academy of Sciences.

The California Academy held its regular meeting last Monday evening. A large number of new members were elected, probably one of the beneficial results of the recent donation to the Academy, by James Lick. They were as follows:

Life Members.—Mark L. McDonald, Coll Dean, H. L. Hill, E. J. de Sta Marina, F. E. Wilke, F. Locan, Louis Sloss, R. H. McDonald, James T. Boyd, W. B. Hooper. *Resident Members.*—Lawrence Kilgour, J. D. Howell, J. W. Roper, A. W. Von Schmidt, Michael Deering, Jacob Best, W. A. Aldrich, A. B. Forbes, J. H. Haley, J. H. Blumenburg, R. B. Irwin, S. D. Field, J. N. Smith, O. P. Evans, J. A. W. Lundberg, General J. F. Miller, J. C. Woods. *Corresponding Members.*—M. Lindeman, Otto Finsch, Alexander Willard.

The egg of an Australian Emu was presented by Mr. Fischer. A Gros, druggist, presented specimen of worm drawn from the pipes of the Spring Valley Water Company. Dr. Kellogg presented and read a description of the following new shrubs and plants: A new native of the oleacea or olive family. *Henchero Californica*, a new species of alum root, collected by Dr. Kellogg and S. Brannan, Jr., at San Gregorio Creek, May, 1870. *Lagophylla minima*, or little hare's foot, a mycopoid composite, with the aspect of a dwarf life, everlasting, collected by S. Brannan, Jr., at Oakville, Napa county. *Trifolium pauciflorum*, a dwarf species of clover from Cisco, Sierra Nevada Mountains, found at an altitude of 6,000 feet. *Solidago elongata*, the small flowered golden rod found on Kimball's farm, at Webb's Landing. *Erigeron Discoidea*, or nodding rayless flea bane; also, several specimens of the giant sunflower.

A paper, by Theodore Gill, was read "on the *Scombrotoxis salmonens*, of Peters and its identity with *Anoplopora fimbria*." This was in relation to a form of fish existing at Vancouver Island.

R. E. C. Stearns read a paper on wood-eating marine animals. The proceedings of this meeting were of little general interest.

THE STRIKES expected in New York have not been made as anticipated. The Presidents of several divisions of the Laborers' Union Benevolent Society were present at a recent meeting in New York and stated positively that no strike would be made, as the members were satisfied with their wages and hours. It is said the whole story originated as a newspaper sensation.

BRISTOL DISTRICT, Nevada, is excited over rich discoveries of silver.

GERMAN MINING COMPANIES.—We learn from Germany that, owing to the removal of the political uncertainty which before the late war had kept industrial enterprise in constant check, business has been exceedingly prosperous. The following is a list of dividends lately paid:—Erzgebirge Coal Company, Zwickau, 80 per cent.; Fortuna Coal Company, 70; Zwickau Coal Company, 45; Harpen Coal Company, Westphalia, 25; Neu-Essen Coal Company, 20; Holland Coal Company, 22; Concordia Coal Company, Oberhausen, 10; Aplerbeck Iron Works, 12; Herde Iron and Steel Works, 8; Styrum Iron Industry, 18 Thale Iron Works, Hartz, 20; Tarnowitz Iron Company, Silesia, 18; Stolberg Lead and Zinc Works, 8; Griesheim Chemical Works, 10; Berlin Engine Works, 11; Cologne Engine works, 12; Chemnitz Engine Works, 22½; Chemnitz Engine and Tool Company, 14.

Decision in Regard to Swamp Land in California.

A letter has been addressed to the Commissioner of the General Land Office to the Surveyor-General of California, establishing important principles in regard to swamp land grants to various States under the Act of July 23d, 1866. The questions decided hereby arose in reviewing the action of the Surveyor-General of California on a large tract of alleged swamp land, known as Big Meadows, and situated in a valley in the Sierra Nevada.

Commissioner Drummond says: "In your report you refer to the altitude of the lands under consideration. As the same point was made by the attorney and considered by you as a reason for rejecting the claim of the State in the Sierra Valley case, and also in that of Mountain Meadows, I again allude to the subject for the purpose of saying that it makes no difference how high or elevated the lands may be, if they are in fact swamp or overflowed, and rendered unfit for cultivation by water flowing from surrounding lands still higher.

While very low lands may be perfectly drained so as to be susceptible of cultivation, marshes and lakes are found in most elevated regions, and dry lands in low valleys; therefore each case must be decided upon the facts. The question to be determined is not one of altitude, but of quality. If elevated lands are found to be swamp or overflowed, and thereby rendered unfit for cultivation, they must be awarded to the State under the grant; and if low lands are found to be dry, the claims of the State must be rejected.

"Another point urged by the attorney, and considered by you as a cause for rejecting the claim of the State, is that the lands produce wild grass, which is valuable for pasturage and hay. Natural productiveness has no bearing upon the question except as evidence tending to show the character of the lands; and the fact that the lands produce wild grass fit for pasturage or hay is not evidence for or against their swampy character, unless we take into consideration the kind of grass produced. Some kinds of grass grow on dry lands only; others grow on swampy lands only.

The question to be considered in this connection is, not whether the lands in a natural state produce something of value, but whether they are so swampy or overflowed as to be rendered thereby unfit for cultivation. If they are, they go to the State, under the grant, however valuable their natural productions may be. But if they are in fact dry, they do not inure to the State, although they may be unproductive and worthless. A tract of land may be very valuable for its timber, its wild grasses or cranberries, and yet be clearly and unquestionably swampy or overflowed and unfit for cultivation until drained or reclaimed.

A cranberry marsh may in its natural state enrich its owner, and yet be so swampy as to render it impossible to cultivate the land. On the other hand, a tract of land perfectly dry may be unproductive and utterly worthless. Therefore I think it is clear, that while the natural state or condition of the land is to be considered as determining the right of the State, the kind, quality, or nature of its natural productions are not matters of consideration except so far as they may be evidence of the character of the land.

"Another point urged in these cases against the claim of the State is, if the lands should be drained, irrigation would become necessary to the production of crops. This is a virtual admission of the fact that the lands are swampy, and I cannot see how irrigation or anything else necessary to cultivation after reclamation can affect the right of the State to them under the grant, if they are swampy or overflowed in their natural State.

The attorney opposed to the State asserts that irrigation is a part of cultivation. He is undoubtedly correct. Therefore it would be just as unreasonable to decide that the lands are not swampy, because it will become necessary to plow them after they are drained to make them productive, as it would to decide that they are swamp lands because irrigation will become necessary for the same purpose.

The testimony fails to show that other crops than grass could be produced, if the land were reclaimed. On the contrary, it is in evidence in all cases investigated in regard to similar lands, such as the Sierra Valley and the Mountain Meadows, as well as land now under consideration, that good crops of potatoes, oats, beans, peas, barley and even wheat can be grown successfully, and had been grown on such lands as were free from water early in the season.

After a careful examination of the evidence, Commissioner Drummond approves the California Surveyor-General's decision that some 6,280 acres of the tract in controversy are not swamp and overflowed, within the meaning of the Swamp Land Act, and that 680 acres are swamp lands. In regard to the remaining 1,420 acres, Drummond reverses Hardenbergh's decision, and decides that they are also proved to be so overflowed in a majority of seasons as to be unfit for cultivation, and must be awarded to the State.

This decision affects large interests of the Central Pacific Railroad Company, as much of their land involved in similar controversies will be included in their land grants if not patented to the State of California as swamp and overflowed.—*Call*.

The Oxy-Hydrogen Furnace.

Mr. Levi Stevens, patentee of the Stevens furnace, which has been described at length in our columns, gives his own views on the operation of the furnace to the *Bulletin* as follows:

Will you allow me space in your columns to explain to the public my invention from my standpoint? Much has been said about burning water or steam, and many seem to entertain the idea that I claim to burn steam as steam, and from some statements I have heard I have been led to believe that I was not only burning steam but water with it. I do not wish to stand before this community, or any other, as the advocate of such a theory, or have any one suppose I am advocating it. Water is the product of combustion; it cannot enter into combustion itself until the gases composing it are separated and changed; then they cease to be steam or water? What I claim is that I have discovered conditions by which a highly combustible gas or vapor is formed of the combined vapor of steam, and hydro carbon, and the hydrogen of the steam is set free to take on its equivalent of oxygen again at the point of combustion. The laws which govern in this, as throughout nature, are positive and uniform, and when understood become subservient to man. It is a well-known fact that as you increase the temperature of water or steam, you destroy the electric cohesion between the hydrogen and the oxygen, and their affinity for each other; it is equally well understood that as you increase the temperature of carbon you increase its attraction for oxygen. This conceded, what remains to be done is to establish such conditions of heat as will destroy the attraction of the hydrogen for the oxygen, and increase the attraction of the carbon for the oxygen to such an extent that their relations are changed and a new combination formed. The conditions best adapted to promote this new combination or association of gases, so far as I have been able to determine, are to heat the steam to the temperature at which the carbon or hydro-carbon is decomposed, and to hold the steam and hydro-carbon vapors under pressure, or the pressure of the volume of escaping steam before they are ejected into the furnace. The necessary conditions for carrying on this process are established with the waste heat. Carbon, in perfect combustion, gives about 800 units of heat. Hydrogen gives about 3,300 units. If my positions are well taken, and I am not deceived, I get not only the 800 units of heat from the perfect combustion of the carbon, but 3,300 units from the combustion of the hydrogen eliminated from the steam.

I am confined to no particular form of carbon or hydro-carbon. Bituminous coal, wood, asphaltum or petroleum, all and every kind of carbon, are equally well adapted, and can be used by establishing such conditions that the gases are thrown off and used with steam, and the coke and charcoal burned in connection with the gases on grate bars or in the furnace.

AN EXPECTED STRIKE.—The telegraph informs us of an expected labor strike in New York, which if carried out will be seriously felt. It is said to be near at hand. The Eight-hour League claims to have \$100,000 in the treasury, and say they have doubled their means since the struggle of last year. Carpenters, plasterers, stone-masons, brick-layers, stair-builders, plumbers and house-smiths are now working on the eight-hour system, and, though satisfied with their present wages, they will strike against the contemplated return to ten hours. The piano-makers, upholsterers, varnishers and cabinet-makers are working ten hours, but are holding secret meetings to discuss the expediency of another eight-hour strike. Over fifty different Trades Unions in New York are committed to the eight-hour movement, and the probabilities are that many branches of manufacture will be disorganized this spring and summer.

ENGLISH RAILROAD IRON.—The quantity of railroad iron exported from Great Britain last year, amounted to 947,548 tons valued at the sum of £10,237,768. The value of this iron was unprecedented in the history of English iron-making, although the quantity exported has decreased since 1870. In that year there were 1,059,392 tons exported, but its value was only £8,756,552. The largest single customer for this iron was the United States, which took 472,760 tons last year, against 512,277 tons in 1871 and 421,824 in 1870. The total amount of railroad built in this country was 7,613 miles last year, while it was 7,878 miles in 1871 and 7,430 in 1870. The large sum obtained for the single item of railroad iron by England for one year gives us a good idea of the value of the iron interests of that country.

THE VIRTUE MINE.—The Baker City Democrat of February 26th says: "We are informed that the Virtue Mining Company intend to put up a new quartz mill this season, with twenty stamps; the mill will be located at the ledge about eight miles from Baker City. The necessary machinery was shipped from Portland to the Dalles the latter part of last month, and teams were immediately loaded at the Dalles with the machinery, and it is now on the road to this point. We understand that all the machinery in connection with this mill is of the latest improvements, and when ready for work will be as complete in all particulars as any on the coast.

Safety in Coal Mines.

Experiments are being made in the Catacombs of Paris to illustrate the efficiency of a new apparatus for preserving the life of miners against fire damp. The experiments, aside from the novelty of the situation, are rendered quite interesting from the strange manner they are carried on. In the center of a large opening is placed a large glass box or chamber, in which is placed a rabbit and a rooster. At the extremity of this chamber is a tin cylinder, closed at both ends, and an india rubber tube inserted in one end. A man dressed like a miner enters the glass chamber which is closed on him hermetically and proceeds to work with a pickaxe as if in a mine. He has on his back a small tin box, like a knapsack. The nostrils are closed by means of a spring like the central part of a pair of spectacles, and he holds in his mouth the end of a tube which connects with the tin box on his back. He tears up the ground and works around as if in a mine. The knapsack is intended to hold a supply of pure air and the tin cylinder a reserve fund of the same article. The glass chamber is then filled with carbonic acid gas, which in a few minutes kills both the rabbit and rooster. The lamp on the miners' breast burns, as it is supplied also with air from the can, but the torches in the chamber are of course extinguished. When the light of the lantern grows dim he draws upon the reserve fund of fresh air. Hydrogen and oxygen gas are then turned into the glass chamber but have no effect, the lamp being a safety lamp, and he himself being independent of the surrounding atmosphere.

The device is that of Captain Denarouze, who hopes to introduce it in coal mines particularly. Something of this kind has long been in use but was not intended for regular work. In cases of emergency, a bag of air was placed on the miners' back, his nostrils closed and a tube connecting with the bag placed in his mouth. By means of this device however, it would seem as if men could work for some hours, and the knapsack and cylinder replenished as occasion demands. If miners perish of choke damp after this, it will not be through the fault of science.

The Limestone Belt of California.

In the chapter on California in the U. S. Mining Commissioner's Report for 1871 occurs the following interesting paragraph:

Another prominent feature in the geology of this part of the country is the limestone belt, on which are found the early placers, noted for their immense yield from 1850 to 1855. This belt runs through all the southern mining counties, and can be traced continuously for nearly one hundred miles. Its course is northeast and southwest, and its width varies from half a mile to three or four miles, in some places contracting, at others expanding. At Sonora it is narrow, while at Shaw's Flat and Columbia, a few miles farther north, it is several miles in width. Throughout its entire length it was noted for the richness of its placer deposits, which were, however, merely superficial, rarely exceeding in depth six or eight feet, except in places where the limestone formation contracts, and at these points it has been worked to a depth of from forty to a hundred feet by following and cleaning the crevices. Throughout its length the limestone bed-rock has been deeply worn by the action of swiftly running water carrying boulders and debris, which have cut and carved it in the most singular and fantastic shapes to a depth of many feet. In many places remarkable underground caverns of unknown extent are found. One of these, exists near Cave City, El Dorado County, of many acres in extent, which has never been thoroughly explored, although discovered as early as 1852.

The rich flats near Columbia and Springfield, when discovered by the early prospectors, were covered with dense growths of pine, and the entire face of the country has been so changed by mining operations as to be unrecognizable to the miner of '49-'50. The richest portion of the limestone belt has been found on the east side of Table Mountain, in Tuolumne County, and it is very probable that the placers owed much of their wealth to the scattering and distribution by water of portions of the Table Mountain channel not protected by lava. There is strong evidence of the correctness of this opinion near Springfield, Columbia, and Shaw's Flat—all of these places being but slightly below the level of the ancient channel at its exposed points. These towns, and Sonora, Jamestown, Montezuma and Chinese Camp, owe their existence to this class of placers. Near the head of Table Mountain, where the basins and crevices on the limestone belt are deep, we find the towns of Murphy's and Vallecito, in Calaveras County, where mining is still prosecuted on a small scale by means of whips and pumps, with a fair profit, but the ground remaining to be worked is limited. At these points the Table Mountain is much broken up

and loses its identity as a continuous range. The "flats" between the monad-like elevations have proved exceedingly rich, but all efforts to drain them have proved pecuniary failures in consequence of the great length of tunnels required.

The towns of Columbia, Springfield and Sonora, once the most populous of the Southern mines, were built on the best placer ground, and town lots are now more valuable for mining purposes than for business and residence. Placer mining in their vicinity has been virtually abandoned to the Chinese, who are satisfied to work ground which has been panned through the sluice-boxes two or three times. It often happens in these towns that a lot with a brick house on it is bought and the house torn down, merely for the purpose of taking the gold from the ground. As some of these towns are very much decayed, property of this kind can be bought for prices which leave an ample margin of profit after sluicing out the ground.

Forest Culture

While on our last weekly tour after items, we visited the farm of our pioneer forest planter on this coast, Mr. James T. Stratton, about two miles north east of this town, and were surprised at the astonishing growth the trees on his Eucalyptus Plantation have made during the past year. We have referred briefly to this enterprise several times, but as forest planting is largely engaging the attention of our farmers at the present time, and indeed of all who feel interested in the future welfare of our State, we think a more extended description of it would be interesting to our readers.

Until the practicability of forest culture was demonstrated by Mr. Stratton the opinion was generally entertained that we would always be compelled to depend entirely on distant points for our supply of the hard woods. The example which has thus been set will be worth millions to our State, and already we hear of several capitalists who are contemplating a like venture on a large scale. We learned from Mr. Stratton that his intention was first directed to the subject of forest culture in 1869, while observing the wonderful growth of the Eucalyptus or Australian Gum tree at his residence in Oakland, and having in April of that year secured all the seed he could obtain from them he immediately planted them in a nursery and succeeded in raising about 40,000 young trees; about 30,000 of which he planted in November and December of that year in a permanent plantation, 8 feet apart each way, covering about 54 acres. These were all the variety Eucalyptus Globulus or Blue Gum of Tasmania, are now generally 35 to 40 feet high and from 5 to 9 inches in diameter 2 feet from the ground.

In the spring of 1871 he planted about 50,000 more Blue Gum, covering about 60 acres; choosing for this planting a high hill, the soil of which is quite sandy and is classed, by farmers, among the poorest soils in this vicinity. Every one predicted a complete failure in this field and old practical farmers were inclined to question the judgment of their new competitor for agricultural honors, but the result shows that he acted wisely, as the trees are perfectly at home, and are making a growth nearly equal to that of the first planting, which was on rich valley land. A month ago these trees were from 12 to 25 feet high and 2 to 4 inches in diameter, but the proprietor has recently had them cut back to 10 feet to prevent them from becoming top heavy and hence liable to be blown down when the ground becomes soft during our long rains. In the spring of 1872 he added to the hill 20,000 more trees of various varieties—Blue Gum, Red Gum, Iron Bark, Stringy Bark, &c., all of which are doing well and looking as healthy as if they were growing on their native Australian hills.

Since the enterprise was started the medical value of the tree has been discovered, and the hospital experiments that have been made by Dr. J. S. Coleman in San Francisco indicate that the extract of its medicinal properties is doubtless destined to become a valuable substitute for quinine as an anti-periodic tonic and febrifuge, and that it is an invaluable remedy in diseases of the kidneys, bladder, &c. So abundant is the active medicinal principle in the leaves of this tree, as determined by Dr. Coleman's experiments that should quinine be entirely supplanted by the new remedy, Mr. Stratton estimates that his Eucalyptus forest alone could supply the demand for the whole United States.

As we have stated the trees of the first planting are 8 feet apart, those subsequently planted being 6 by 8 feet apart. It is intended to bring to cut out the poorer and scrubby trees when they are about five years old, and a second cutting about two years later, leaving about 150 on an acre to remain for timber. These earlier cuttings will only be useful for fuel, but will pay all the previous cost of the enterprise.

He expects to begin cutting for timber at 10 years from the seed and thinks that he will then be able to show clear logs 12 feet long and 15 inches in diameter, worth at least \$5 in the tree and that in 20 years he will have trees 100 feet high and 2 feet in diameter, and from our own observations on the growth of these trees in different localities we believe his expectations will be realized.—*Alameda County Advocate*

DEWEY & CO.

MINES, MILLS, AND FURNACES

OF THE
Pacific States and Territories.
An Account of the Condition, Resources, and Methods of the Mining and Metallurgical Industry in those Regions, Chiefly Relating to the Precious Metals.
A Sequel to "AMERICAN MINES AND MINING."
By ROBERT W. RAYMOND, Ph. D.,
U. S. Commissioner of Mining Statistics, Etc., Etc.

CONTENTS.

INTRODUCTORY—PART I—CONDITION OF MINING INDUSTRY. Chapter I—California; II—Nevada; III—Oregon; IV—Idaho; V—Montana; VI—Utah; VII—Arizona; VIII—New Mexico; IX—Colorado; X—Wyoming.
PART II—METALLURGICAL PROCESSES. Chapter XI—The Treatment of Auriferous Ores in California; XII—The Speed of Stamps in Colorado and elsewhere; XIII—The Washoe Iron Amalgamation; XIV—Chlorination; XV—Smelting Silver Ores; XVI—List of Stamp Mills.
PART III—MISCELLANEOUS. Chapter XVII—Narrow Gauge Railways; XVIII—The Mining Law; XIX—The Geographical Distribution of Mining Districts; XX—The Origin of Gold, Silver and Gold Dust; XXI—The Bullion Product. Appendix.
Sold, wholesale and retail, by DEWEY & Co., Publishers of the MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$3.50; postage, 50 cents.

New Inventions.

A GRATE BAR that don't burn out, for furnaces.
SHEARS for cutting grapes and flowers.
A NEW ROLLER SKATE that is superior to all others. \$6.
A DRINKING FOUNTAIN for fowls. \$1.25.
A superior ROAD SCAPER.
The cheapest and best FENCE EVER built.
A POST DRIVER that every farmer should have.
An improvement on DENTAL PLATES to hold them firmly in the mouth.
A NEW FURNACE for roasting ores.
A SASH TIGHTENER that keeps out all dust, takes the place of weights, and keeps the windows from rattling.
A BED SPRING that never gets out of order.
A SALT CAP that keeps all dust out of hubs.
A POTATO DICER that will dig a row as fast as a man can walk.
A HOUSEHOLD TOOL needed in every family. 50c.
A self-acting NUT ROASTER that works to perfection.
A NEW GAS LAMP that costs only half a cent per hour to burn.
An improvement in TRILL ATTACHMENTS.
A superior ORDER and WINE PRESS.
The best SELF-OPENING GATE ever invented.
A PLOW on a new principle—it works to perfection in adobe.
A NEW VEGETABLE CUTTER for house use.
An improved PLOW CLEVER.
A simple, cheap and perfect POLISHING and FLUTING IRON combiner. \$3. Agents wanted.
A TOX BOWNE that every boy should have for instruction.
A new GLASS CUTTER that beats a diamond. 50c.
A CAN OPENER that cuts any shaped hole and every size. 75c.
The best WASH BOILER ever invented.
An EGG BEATER that beats eggs in one minute. 75c.
A WALL PROTECTOR for placing behind wash stands.
A new SULPHURET-SAVING MACHINE.
The LITTLE GIANT COIN SHELTER, for \$1.50 by mail.
KNIFE SHARPENER that should be in every kitchen. 50c.
A CORN HUSKER that husks 400 bushels per day.
The best machine to CLEAN GRAIN in the world.
A new HORN CAMBER, just out.
The cheapest BERRY BASKET ever made.
A HORSE RAKE that has no equal.
A superior LUBRICATOR for Locomotives and Stationary Engines.
A new FIRE KINDLER for 75c.
We invite parties who feel interested in any of the above named inventions to call and examine samples or send for a descriptive circular of the article.

CYANIDE OF POTASSIUM,
Which I can sell upon better terms than any other
dealer on the Pacific Coast.
I make three grades or qualities to suit the require-
ments of different consumers.
I will be glad to furnish prices to any person ad-
dressing me on the subject.

HENRY G. HANKS,
Manufacturing Chemist,
PACIFIC CHEMICAL WORKS, SAN FRANCISCO
24v25-4f

Varney's Patent Amalgamator.

Best Machines Stand Unrivaled.
For rapidly pulverizing and amalgamating ores, they
have no equal. No effort has been, or will be spared
to have them constructed in the most perfect manner
and of the great number now in operation, not one has
ever required repairs. The constant and increasing
demand for them is sufficient evidence of their merits.
They are constructed so as to apply steam directly
into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.
The pan being filled, the motion of the muller forces
the pulp to the center, where it is drawn down through
the aperture and between the grinding surfaces.
Thence it is thrown to the periphery into the quicksilver.
The curved plates again draw it to the center, where it
passes down, and to the circumference as before. Thus
it is constantly passing a regular flow between the grind-
ing surfaces and into the quicksilver, until the ore is
reduced to an impalpable powder, and the metal amal-
gamated.

Settlers made on the same principle excel all others.
They bring the pulp so constantly and perfectly in con-
tact with quicksilver, that the particles are rapidly and
completely absorbed.
Mill-men are invited to examine these pans and settlers
for themselves, at the office, 229 Fremont Street,
San Francisco

Nevada Metallurgical Works.

LEA & PERRINS'
CELEBRATED

Worcestershire Sauce.

Declared by Connois-
seurs to be the only good
SAUCE.
Caution Against Fraud.
The success of this most
delicious and unrivalled
Condiment having caused certain dealers to
apply the name of "Worcestershire Sauce" to
their own inferior compounds, the public
is hereby informed that the only way to
secure the genuine is to ask for LEA &
PERRINS' SAUCE, and see that their names
are upon the wrapper, labels, stopper and
bottle.
Some of the foreign markets having been
supplied with a spurious Worcestershire
sauce, upon the wrapper and labels of which the names
of Lea and Perrins have been forged, L. and P. give
notice that they have furnished their correspondents
with power of attorney to take instant proceedings
against manufacturers and vendors of such, or any
other imitations by which their right may be infringed.
Ask for LEA & PERRINS' Sauce, and see name on
wrapper, label, bottle and stopper.
Wholesale and for export by the Proprietors, Worces-
ter; Crosse & Blackwell, London, &c., &c., and by
Grocers and Oilmen universally. 15v24-1f

22v25-6m

Manna and Honey-Dew.

A paper upon the above subject was read before the Academy of Sciences, at their session, on the 3d inst.,—the paper was based on observations made by Mr. John Applegate, a former long resident in the San Joaquin valley.

Mr. Applegate is of the opinion that both manna and honey-dew descend from the heavens, like frost or mist, and that both are derived from the sweet aroma of wild flowers, which is carried up by the rarified atmosphere, and subsequently condensed and deposited like dew. A portion—the finer, dryer, and lighter particles—may be carried to a higher elevation, and into a cooler atmosphere, where it might condense more in the form of snow, falling in little pellets, as manna. He accounts for the appearance of these deposits in the fall, so long after the great mass of the flowers have disappeared, by supposing the sweet principle to be held in suspension in the atmosphere for a long time, drifting but slowly from the place of its origin. This theory would hardly be admissible, considering that the high winds of summer, in this latitude, and the farther fact that they come mostly from the ocean—a surface from which we can hardly expect much sweet honey-producing aroma to ascend.

Mr. A. alludes to the fact that while the honey-dew never fails to come in the fall, the appearance of manna is rare. He mentions only two seasons in which he has observed it—in the fall of 1861 (or '62) and that of 1872. It is noticeable that on both occasions its appearance followed immediately after summer of immense verdure. It appears only on the morning of the first cool weather in the fall, and covers the foliage and fences somewhat like frost—in the form of small, roundish, whitish grains or particles, quite sweet to the taste, and corresponding very closely with the description in Exodus of the manna upon which the Israelites subsisted during their sojourn in the wilderness; the honey-dew closely resembles that described by Josephine as descending upon the hands of Moses—sticky and sweet. The honey-dew is the sweetest of the two; but it has a ranker taste than the manna, and not so agreeable.

Mr. Applegate also alluded to the peculiarity connected with the collection and storing of this substance by the honey-bee. The bees collect both, and the comb-cells are found filled with both substances, when they are obtainable. The honey and manna, however, are never found in the same cells. The two substances are found in separate cells; but not promiscuously mixed. The cells so filled are found to occupy groups.

The question of the origin of the honey-dew and manna, is one which has never yet been satisfactorily settled. The objections to the above theory are manifest; but the difficulties in the way of attributing it to an exudation or deposit from insects is still greater. The honey-dew, when it occurs, is found covering all surrounding objects for miles. Trees, shrubs, grass, fences, and even the bare earth, are completely covered with it. Even the dry leaves upon the ground are so covered with the sticky substance, that they adhere to the sole of the boot to such an extent as to make its presence very uncomfortable.

It is impossible that it could be deposited in such abundance by the insect referred to, as oftentimes but few of the insects—a large species of the Aphid family—can be found; sometimes not at all, for long intervals.

We have at this office some specimens of the insect above referred to, preserved in alcohol; also some of the honey-dew, slightly diluted with water, in order to render it sufficiently limpid to be transferred to a vial. These specimens were furnished a year ago last fall, by Mr. Frank Carnana, of Greece Valley, and noticed by us at the time.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office, S. F.:

SUCCESS GOLD M. CO.—March 19. Location: Kelly's Quick Mining District, Calaveras county. Capital stock, \$250,000, in shares of \$50 each. Trustees: Herman H. Schaffer, Wm. H. V. Cronise, James L. Trask, R. Kolman and A. Clark.

PACIFIC CHEMICAL CO.—March 16. Object: To manufacture, import and deal in all kinds of drugs, chemicals, chemical apparatus and material pertaining to chemistry. Also to engage in assaying, refining ores, and other chemical processes. Capital stock, \$500,000, divided into 25,000 shares of the value of ten dollars each. Directors—Henry G. Hanks, Charles H. Denison, Geo. A. Treadwell, A. Treadwell and John N. Barber.

PACIFIC ASBESTOS MINING AND MANUFACTURING CO.—March 15. Object: To manufacture asbestos. Directors—S. F. Taylor, Geo. W. Blake, Jesse Cheney, James M. Allen and E. Chamberlin. Capital stock, \$100,000. The amount of stock which has been actually subscribed is \$11,500.

SAN FRANCISCO GAS LIGHT CO.—March 15. Object: Manufacturing and supplying gas and other illuminating materials, and for the supply of gas to the public. Capital stock, \$10,000,000, in shares of \$100 each. Trustees—H. H. Haight, C. B. Oresthouse, Jashel Clement, Louis T. Hays, J. M. Greathouse, Chas. H. Denison, and Howard Hays.

ARIZONA JEWEL CO.—March 13. Object: to mine for precious stones and metals in the Territory of Arizona or elsewhere. Capital stock, \$3,200,000, in shares of \$100 each. Trustees—A. P. Green, A. B. Rosalis, W. C. Reed, G. M. Berry and D. Marucci.

Meetings and Elections.

INUS G. M. CO.—March 15. Trustees—J. H. H. Williams, (President), Wm. Norris, Chas. E. McLane, H. T. Wheeler and T. P. Besch; David Wilder, Secretary. **PACIFIC CHEMICAL CO.**—March 16. H. G. Hanks, President and Superintendent; Geo. A. Treadwell, Vice-President; C. H. Denison, Treasurer; and A. Treadwell, Secretary.

CHAPMAN M. CO.—March 14. Trustees—D. L. McDonald, J. P. Cavallier, H. H. Flagg, Geo. O. Davies and C. A. C. Miller.

The Prayer Gauge.

A correspondent of the *American Artizan*, writes as follows.

Will you permit me to say a few words in regard to the "Scientific Test of Prayer?" The persons have been cured while being prayed for I have no doubt. But it matters little what the religious belief is of the person praying. A prayer uttered in a powerful manner to a Hindoo god of stone in the presence of a Hindoo patient, would, in some cases, be effective. I had a friend that was cured instantaneously by the laying on of hands while being prayed for; yet the author of that prayer believed that the members of all Christian churches will be snubbed.

I can cite instances where the deaf, dumb, and lame have been cured by the laying on of hands.

A person residing in this State was cured of an abscess in fifteen minutes by passes made over the subject.

Now, what is the cause of these remarkable cures? Magnetism is at the foundation of it all—changing the magnetic currents, imparting it where it is wanted, withdrawing it where there is an excess; withdrawing the old and imparting the new.

Anger, jealousy, fright, prayer, love, and revenge, each in the right place, are more or less efficacious. I speak from knowledge, having had an opportunity to study these things. I would not advise any one to cease praying; yet has it occurred to your correspondent, that in those nine days of prayer, millions of prayers were offered for the sick where one or but a few were cured, except through care and medicine? Faith and the imagination have a great deal to do in restoring the sick. W. L.

Leather Market Report.

Reported for the Press by Dolliver & Bro.]

SAN FRANCISCO, Wednesday, March 13, 1873.	
The price of sole leather continues the same. French Calf Skins still have an upward tendency, with prospects of further advance.

Gold Run Mining Company.—Principal place of business, San Francisco, California. Location of works, Nevada County, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the fifteenth day of March, 1873, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin to the Secretary, Corner Market and Spear Streets, San Francisco, California. Any stock upon which said assessment shall remain unpaid on the fifteenth day of April, 1873, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the sixth day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. C. C. PALMER, Secretary. 121-21, Cor. Market and Spear Streets, San Francisco, California.

Hardy Coal Mining Company.—Location of principal place of business, San Francisco, Cal. Notice.—There are delinquent upon the following described stock, on account of assessment levied on the twenty-eighth day of January, 1873, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.

And in accordance with law, and an order of the Board of Directors, made on the twelfth day of February, 1873, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the salesroom of Messrs. Maurice Doré & Co., No. 327 Montgomery street, San Francisco, California, on Tuesday, the eighth day of April, 1873, at the hour of 12 o'clock, m., of said day, to pay delinquent assessments thereon, together with costs of advertising and expenses of sale. Office, 608 Merchant Street, San Francisco, California. 72111

Lady Esten Tunnel and Mining Company. Location of principal place of business, No. 35 New Merchants' Exchange, California Street, San Francisco, California. Location of works, Little Cottonwood District, Utah Territory. Notice is hereby given, that at a meeting of the Directors, held on the 17th day of March, 1873, an assessment (No. 2) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 35 New Merchants' Exchange, California Street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 17th day of April, 1873, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the sixth day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. CHAS. S. HEALY, Secretary. Office, No. 35 New Merchants' Exchange, California Street, San Francisco, California. m22

Lady Franklin Gold and Silver Mining Company.—Principal place of business, city and county of San Francisco, California. Location of works, Silver Mountain Mining District, Alpine county, State of California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 18th day of February, 1873, an assessment of fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately, in gold coin, to the Secretary, at the office of the Company, 507 Montgomery street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the thirty-first day of March, 1873, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the twenty-first day of April, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. J. S. LUTY, Secretary. Office, 507 Montgomery street, San Francisco, California. m22

Mansfield Gold Mining Company.—Principal place of business, San Francisco, California. Location of works, Kelsey Mining District, El Dorado County, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of February, 1873, an assessment (No. 1) of two and one-half cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the company, room 14, 331 Kearny street. Any stock upon which this assessment shall remain unpaid on the 29th day of March, 1873, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 14th day of April, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. WM. SMILL, Secretary. Office—Room 14, 331 Kearny street. mrl

Office of the Phenix Silver Mining Company. San Francisco, March 18th, 1873.—Location of principal place of business, Lander County, State of Nevada. The Annual Meeting of the Stockholders of the Phenix Silver Mining Company, for the election of Trustees, and the transaction of such business as may be presented, will be held at 10 o'clock, April 7th, 1873, at 1 o'clock p. m., at the office of the Company, Room No. 26, Hayward's Building, 419 California street, San Francisco, California. Transfer books will be closed April 4th until after the meeting. JOSEPH MAGUIRE, Secretary. m22

Piermont Milling and Mining Company. Location of works: Piermont, White Pine County, Nevada. Notice.—There are delinquent upon the following described stock, on account of assessment (No. 6) levied on the twenty-fifth day of January, A. D. 1873, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Feusler, Mary P.	35	50	\$25 00

Machinery and Castings of all kinds.

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 125 First street, S. F. 24v234f

Notice is hereby given, that the copartnership heretofore existing between A. J. Severance, Charles W. Randall and J. Gus. Burt, under the firm name of "Severance, Holt & Co.," is this day dissolved by mutual consent. A. J. Severance, having purchased all the interest of his late partners, will continue the business of manufacturing and selling Diamond Drills as before, under the style of A. J. Severance & Co. Dated San Francisco, Nov. 24, 1871.
Office, 315 California street. A. J. SEVERANCE,

best manner. No. 32 Fremont street, S. F. 19v23-3m

The California Powder Works

No. 314 CALIFORNIA STREET,

SAN FRANCISCO.

Manufacturers and have constantly on hand

SPORTING.

MINING,

And BLASTING

POWDER,

OF SUPERIOR QUALITY, FRESH FROM THE
MILLS. It being constantly received and transported
into the interior, is delivered to the consumer within a
few days of the time of its manufacture, and is in every
way superior to any other Powder in Market.
We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

We also call attention to our

HERCULES POWDER.

Which combines all the force of other strong explosive
now in use, and the lifting force of the BEST BLASTING
POWDER, thus making it vastly superior to any other
compound now in use.

A circular containing a full description of this Powder
can be obtained on application to our Office.

16v20-3m

AXLE GREASE.

To Millmen, Teamsters and Others.

Your attention is called to the very superior AXLE
GREASE manufactured by us for over 18 years.

Recent improvements in the chemical arrangement
of the lubricants used in its manufacture render its use
as serviceable on the lightest buggy as on the heaviest
team.

The extensive demand for the H. & L. Axle
Grease has enabled the proprietors to reduce its price
to as low a rate as any of the inferior compounds,
which are continually being forced upon the market.

See that this trade-mark (H. & L.) is on the red
cover of the package, and take no other.

Duval's Patent Centrifugal Pumps.

BURLEIGH
ROCK DRILLS

—AND—

Air Compressors.

The Burleigh Rock Drills, which have stood the test
of five years' constant use at the Hoosac Tunnel, and
which are now in use in nearly every State in the Union,
as well as in Europe and South America, are unequalled
in efficiency and economy by any other Drilling Ma-
chine. They are of various sizes, and equally well
adapted to Tunneling, Shaling, Open Cut or Quarry-
ing, and will drill six to ten inches per minute in gran-
ite. They are driven by steam above ground. The Bur-
leigh Air Compressor is the best engine yet devised for
furnishing the "air motor" for the many purposes to
which it is now being used.
They are to be used on the St. Gothard Tunnel, Swit-
zerland; Tunnel 13 miles long. We refer to the follow-
ing gentlemen and works:

Gen. Newton, U. S. A.Hell Gate Tunnel, L. I.
Mess. Shanley.....Hoosac Tunnel, Mass.
J. Dutton Steele.....Nesquehoning Tunnel, Pa.
Sidney Dillon.....Fourth Avenue Work, N. Y.

Betts's Capsule Patents.

To prevent infringements, notice is hereby given, that
Betts's name is on every Capsule he makes for the principal mer-
chants in England and France.
Thus enabling vendor, purchaser, and consumer not only to
identify the genuineness of the capsule, but likewise
the contents of the vessel to which it is applied.
The LORD CHANCELLOR, in his judgment, said that the
capsules are not used merely for the purpose of the crim-
inal, but that they are serviceable in protecting the wine
from injury, and insuring its genuineness.

SITUATION WANTED.

An active and thoroughgoing young man, aged 30, is
now open to engagement. Theoretically and practi-
cally understands the complete metallurgy of lead,
silver, etc. Competent to erect and manage reduction
and technical works, of any magnitude, for lead, silver,
antimony, etc., by any process. First-rate assayer and
analytical chemist. References as to character and
ability. Address A. Z., care of Scientific Press. m8-1m

SITUATION WANTED.

A Thoroughly Practical and Theoretical
Miner, acquainted with the mining business in all its
branches—Assaying, Amalgamating, Surveying, Etc.—
wishes employment. Best references given.
Address X. Y. Z., this office. m8tf

BROWN'S PATENT LAMP.

One of these Lamps, when placed at a distance of 300
feet from the bank, will light up a bank surface 250 feet
in length and 150 feet high, and to a much better ad-
vantage than any other light heretofore tried, and at an
expense not to exceed five cents per hour. Lamps
furnished at short notice.

Letter of Recommendation.

Mr. C. B. Brown—Sir: Your Patent Lamp for light-
ing hydraulic mines, which you sold to me in December
last, has given entire satisfaction, and far exceeds my
expectations, and I think it the best and cheapest light
ever used to light mining claims by night, and am sat-
isfied that I have saved three hundred dollars by the
use of it in the last mining season over pitch or any
other light of the same brilliancy; and I will also say
that if I could not get another lamp, five hundred dol-
lars would not buy it. Yours, W. D. APLIN.

Little Rock, Nov. 5, 1872.

For further particulars, address,
1622-4f **C. B. BROWN,** Placerville, Cal.

P. J. PHILLIPS & CO., No. 608 Clay street, near
Montgomery, San Francisco, are agents for Brown's
Lamp, where it may be seen.

EUCALYPTUS.

The attention of the Medical profession is respectfully
called to the following preparation of this new reme-
dial agent. Eucalyptus and its preparations have been
found useful in obstinate cases of intermittent and Marsh
Fever, often supplanting the use of Quinine. The
paroxysms of Asthma and Catarrh are greatly controlled,
and in various Kidney diseases and Catarrh of the Blad-
der it seems to act like a specific.

FLUID EXTRACT EUCALYPTUS.

This extract represents in a concentrated form the
medicinal effects of the leaves of Eucalyptus Globulus
THE ELIXIR OF EUCALYPTUS.

This compound presents the properties of the leaves
in a palatable form and elegant appearance. Dose—
One tablespoonful, to be repeated as often as the case
demands.

Cigarettes of Eucalyptus Globulus, useful in
Asthma, Difficulty of Breathing, Incipient Pleurisy, etc.
Prepared and sold by **JAMES G. STEELE & CO.,**
Chemists and Apothecaries,

Scaling and Foaming Prevented and Fuel Saved.

Engineers are respectfully informed that

WARSON'S AERO STEAM SYSTEM

Has been well tested, during three years, in England. Besides the above advantages, it greatly prolongs the life of Boilers, Tubes and Fire-boxes.

It is a cheap contrivance, and easily applied to any engine.

Illustrated Circulars, showing the appliance and describing its advantages, are sent to all applicants.

All who are troubled with Scale and Foaming may rely on this system of prevention—also on saving at least 20 per cent. of fuel.

RIGHTS for States and for individuals will be sold on liberal terms.

J. L. SANFORD,

General Agent for United States,

420 Montgomery street, San Francisco,
And Box 989, P. O.

Information Required to Give an Estimate of Warson's Apparatus:

- 1.—Diameter of Cylinder.
- 2.—Length of Stroke.
- 3.—Number and Length of Boilers—Tubes or Flues.
- 4.—Distance of Boilers from Engine.
- 5.—Can Pump Piston be attached to Cross-head of Engine?

If can, however, be driven by any of the usual appliances that work the Water-feed Pump.

These items will enable me to give a near estimate of the cost.

J. L. SANFORD, General Agent.

IMPORTANT TO Quartz Mining Companies.

IMPROVED PATENTED

Hardened Cast Steel Shoes & Dies.

The undersigned are prepared, at short notice, to furnish IMPROVED PATENTED HARDENED CAST STEEL SHOES AND DIES, for Quartz Mills of every pattern, never chipping from the edges. This, with the time saved in replacing worn and broken iron Shoes and Dies, and the great saving of freight to remote mills and mines, makes a vast difference in the cost of reduction of ores.

They are more economical and cheaper than CAST iron shoes, as they wear from four to six times as long, and crush a greater quantity, as they retain their full diameter, never chipping from the edges. This, with the time saved in replacing worn and broken iron Shoes and Dies, and the great saving of freight to remote mills and mines, makes a vast difference in the cost of reduction of ores.

WE ALSO FURNISH

Cast Steel Tappets, Cams, Picks and Hammers,

Which possess the same advantage of Economy and Durability, and deserve the special attention of Miners and others engaged in quartz crushing.

The Superior Strength of these steel castings—so fast that they can be FORGED AND WELDED as easily as bar steel—their cheapness and great accuracy, as compared with forged iron—cannot fail to make them desirable for many purposes, where forged iron and steel have heretofore been used. Among such articles we mention:

ROLLING MILL CASTINGS.
Bevel and Spur Wheels, Guides, Spindles, Dies, etc. AGRICULTURAL CASTINGS.
Reaper Guards, Plow Shares, Mold Boards, Plow Jointers, etc.

Anvils, Sledges, Vices, Masons' Hammers, Blacksmith Hammers, Mattocks, R. R. Frogs, etc. And other articles requiring solidity and great strength.

DONKEY ENGINES FOR HOISTING,
Mining Machinery, Etc.

Persons giving orders will send diagrams and measurements of Shoes and Dies, etc., as above.

They have proved to be the most durable and economical Saws in the World.

Each Saw is Warranted in every respect.

Particular attention paid to construction of

Portable & Stationary Saw Mills.

MILLS FURNISHED AT SHORT NOTICE
At the lowest Market Prices.

HALLIDIE'S

Patent Endless Wire Ropeway.

Covered by Numerous U. S. Patents.

IMPORTANT TO

Mining Companies, Civil Engineers, Contractors, Etc.

The system of transporting material, such as Ores, from the mine to the mill, Earthen embankments, Rock from quarries, etc., by means of steel wire rope, has been well tested and found more economical, advantageous and reliable than any other method of transportation; and to the annexed certificates in connection therewith I beg to call the attention of those interested:

EUREKA, Nevada, July 10, 1872.
T. M. MARTIN My dear Sir: On your leaving for San Francisco, it gives me great pleasure to hand you my written acceptance of the HALLIDIE TRAMWAY put up by you upon our mine in Freilburg.

It is a perfect success, discharging ten tons of ore per hour with two men's labor. It is perfectly simple in construction, and, as far as I can judge, there is nothing about it to ever get out of order, nothing to wear out. While ours requires but about two thousand five hundred feet of wire rope, I can see no reason why the line could not be extended almost indefinitely with equally happy results. Again, the carrying capacity might be doubled or quadrupled if desired. After several weeks trial upon our mine, the unanimous verdict of all who have seen it is a complete, unquestioned success. If this can be of any service to you, use it in the way you think proper. Very respectfully, O. O. GOODWIN.

EMMA HILL CONSOLIDATED MINING CO.,
Little Cottonwood, Utah.
Superintendent's Office, Sept. 28, 1872.
T. M. MARTIN, Esq., Sir: The Ropeway constructed by you (HALLIDIE'S PATENT) for the Emma Hill Consolidated Mining Company, has been built in a most substantial and workmanlike manner, and is at this time in splendid working condition. I most cheerfully accept the work for the Company, and recommend it to others wishing a sure and speedy transit for ores over places impracticable for wagon roads, etc. Respectfully,
L. W. COLBATH, Superintendent.

"The Vallejo works smoothly with the elevated wire tramway, which carries its load of ore as quietly and easily as if there was no winter or snow in the world."
"Whatever the objections to wire tramways may be on account of their cost, I have seen nothing yet that even approaches them in the facilities they afford for moving ore at all seasons of the year."—Correspondent Utah Mining Journal, Alta, Jan. 8, 1873.

The Vallejo Ropeway.
The Vallejo Tunnel Company's Tramway—Little Cottonwood, built on the HALLIDIE PATENTED PLAN, is a complete success. It is between 2,300 and 2,400 feet in length, and is supported by thirteen stations. The fall in this distance is about 80 feet, and the wire rope, which is three-fourths of an inch in diameter, will safely and easily deliver one hundred tons in six hours. The machinery is automatic, loading and unloading the sacks or hoppers. About one t and a half can be sent down at one time. The stations are about two hundred feet apart, and the entire apparatus is strong and safe. As the wire rope is elevated above the level of the surface of the hill, the tramway can be worked all winter long, without the slightest trouble.—Utah Mining Journal, Salt Lake, Sept. 23, 1872.
Mining Companies and others desiring to negotiate for the erection of this system of Ropeway, can communicate with me personally, or through Postoffice Box 944.

A. S. HALLIDIE, Patentee,
112 and 114 California Street, SAN FRANCISCO.

WIRE ROPE

For hoisting from mines, tram-mitting power, ship rigging, etc., of all kinds and sizes, on hand and made to order. Wire of all kinds and descriptions, furnished at lowest rates. A. S. HALLIDIE, 112 and 114 California St.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and Progressive Industry.

BY DEWEY & CO.,

SAN FRANCISCO, SATURDAY, MARCH 29, 1873.

VOLUME XXVI.
Number 13.

California Miners.

California miners are with regard to morals a much abused class of men. The impression prevails away from this coast, and to some extent here, that their nights are mostly spent in the gambling saloon, brothel and in riotous dissipation. This is far from being the case, generally speaking, although wild and adventurous spirits do exist among them probably to a greater extent than among those who follow other pursuits. For this reason many suppose them all a demoralized set of men. It must be remembered that they are by force of circumstances comparatively isolated from the influence of female society, and men will naturally degenerate in such cases in some degree as far as social relations are concerned, but that they become entirely demoralized is a mistaken idea. The early pioneers who made the paths for future civilization and progress on this coast, were comparatively wild and lawless. Comparatively, we say, because there were no laws in the country and no one authorized to enforce them if there had been, and the evil spirits among them compelled the steadier portions to take the law into their own hands for self-protection—the natural law recognized even by the courts. The cases where such action is necessary in later days are few and far between. Still we who now reap the benefits which the hardihood and perseverance of these early-comers, aided in a great measure to confer upon us, should take into consideration the circumstances under which they lived, before pouring out wholesale condemnation on their courses of life, looking only on the dark side.

The miners employed at large mines, near the more prominent mining towns on the coast are naturally more subject to temptation than those whose claims are in isolated cañons among the mountains and who work their own claims. Although many of the men in the former instance "hach it" in their own cabins, the majority of them find it more convenient to board at some boarding house or hotel. As a consequence they often spend their evenings in the common sitting rooms of such places, or in saloons, unless they keep their own rooms. The round of amusements is exceedingly limited, and they fall back on bean poker, seven up or cribbage, to while away the time. Whether money is put up on the games or not is a matter of individual opinion; but when it is, the amount is generally small, except among regular gamblers who exist in every community and with whom we have nothing to do.

But let us take these men who live in their own cabins on the outskirts of small mining camps, or in isolated localities beside their claims. In California a great majority of the miners are among this class, who if they do not have claims of their own, work on mines which may or may not be incorporated, but whose stock is not called at our Stock Board. There are thousands of such mines scattered all over

the mining counties of the State from the most northern point to San Diego. The men join together in parties of four or five and some of them work for wages while the others work in the claim. When a little hard up, perhaps, the whole party will go to work in some mine for wages until able to work on their own claims again. Sometimes two men's wages will keep four others in "grub." These partnerships are conducted as honestly as if the partners were bound by all the legal documents possible, signed, sealed and recorded, whereas it is seldom that a scrap of paper is held by any of them. They divide the work and di-

camp fire. Black coffee, boiled beans, fried bacon, bread baked in a Dutch oven, or pancakes, form their frugal meal. But it is eaten with a relish that an epicure would envy, for industry, early rising, and regular habits are great promoters of appetite and digestion. Beside the cabin are the utensils with which they pursue their daily toil, and handling a pick or shovel invariably drives away dyspepsia.

Now let us take a peep inside the cabin and see what the domestic arrangements are. Somewhat neater than one would suppose from the appearance of the outside. No paper or cloth on the walls to be sure, but the nails

going repairs. The beds consist of a couple of pair of blankets without sheets or coverlet, made up on a straw mattress, with a coat or two for a pillow.

In a cabin such as we have attempted to describe does many an honest miner pass his time when not working in his claim. The evenings are passed in reading, smoking, talking and playing cards as each may desire. Those who wish to, may take a drink from the demijohn when they please, but drunkenness in such places is seldom seen. Those whose tastes lie that way usually pander to them when in town and semi-occasionally, but not when in their cabins. In places like this the most illiterate will take an interest in a book once in a while, and those who love to read pore over any stray volume which comes in their way with real enjoyment. The conversation of these men, like that of sailors, smacks of their calling. When "cabin-ing" together they will stick up for their "pards" through thick and thin, cheerfully take their share of the allotted household work, and should one of their number be sick he has the best possible care and attention. They take pride in their skill at cooking and in everything they have, except perhaps, their personal appearance, which they think, like Mr. Toots, "is of no consequence."

These men do not care a cent what the outside world thinks of them. They do their work and mind their own business and do not want any one to meddle with it. But as far as being all, or most all,

gamblers, desperadoes, drunkards, etc., as many people suppose, any one who told them so personally would find a fight on his hands as quick as if he killed a rat down in one of the levels of a mine on the Comstock lode.

FISHERY CULTURE.—The Sacramento Record says that Livingston Stone, Deputy United States Fish Commissioner, left for the East on Tuesday, and by the request of the Fish Commissioners of California, will send to this coast large quantities of eggs of various kinds of fish, among them black bass, silver eels, Schuylkill catfish, yellow perch, glass-eyed perch, lobsters, and 100,000 shad. In distributing these fish careful attention has been given to the existence of conditions best suited to their culture. The black bass will be first placed in the artificial ponds owned by A. T. Dewey, of Oakland, from whence they will be distributed throughout the State, and especially in the chain of lakes along the Sacramento river, commencing the first below Sacramento. The eels will be placed in the Sacramento below the R street levee. The catfish will be placed in Clear Lake. The shad are assigned to the San Joaquin; a portion, however, will be placed in the Sacramento above Tehama. The lobsters will be placed in Raccoon Straits.

THE LABOR STRIKE.—It seems that the strikers of the International Association will probably come, after all, judging from telegraphic reports from the East. Members of that body think that all the sections and trades should strike this year to enforce the eight hour law.

MINERS AROUND THE CAMP FIRE.

vide the profits or the loss as the case may be. These men are the representative miners of California. If the traveler goes among them he will find them courteous, hospitable, generous to a fault, sober, steady, hardworking men, and though rough in exterior habit, overflowing with the "milk of human kindness." Among them are many well educated men who are trying to make "their piles" in the mines but they cannot be distinguished from the rest of the crowd unless by their conversation. These miners are more regular in their habits than the generality of people in large cities. Early hours at night are the rule and they rise early by force of circumstances.

Let us make a little sketch for the uninitiated, not fanciful but well remembered by the writer, of the domestic arrangements of this class of men. One cabin is the type of the majority, for though they may differ in detail as to appearance and arrangements, the same general characteristics are common to all. The engraving shown on this page will serve to give an idea to the uninitiated reader of the exterior appearance of an isolated cabin, and a group of miners encircling the fire, while its truthfulness will be recognized by those of our friends who are now among such scenes. The little group have evidently just returned from their claim hard by, and have made a long day of it, for the moon is rising over the tree tops in the background. The "doctor" is preparing supper, the other boys are reading, taking it easy, warming themselves or gathering food for the

driven into the logs would spoil that. Four bunks on each side of the cabin, beside the door, with their heads toward it in a double tier. A small, rough table in the center, with several boxes and powder kegs for chairs, a small looking-glass near the little window with a comb suspended from a string beside it. These catch the eye of the visitor at the first glance. Then he becomes cognizant of some sacks of flour, one of potatoes, in the corner, a few sides of bacon suspended from a beam, a miner's pan or two, an old pick handle, some store clothes hanging from the nails, and a couple of common trunks, and several cracker boxes and carpet sacks, in company with gum boots protrude from under the lower bunks. The walls are ornamented with cuts taken from illustrated newspapers and a few photographs are tacked under two or three of the bunks. On a couple of shelves over the fire-place are a few well-worn books, which show signs of hard service. An old newspaper sticks out of the foot of one of the bunks. At the back of the cabin is the open fire-place in front of which the boys sit on winter evenings. In the summer they prefer to sit outside around the camp fire and smoke their pipes, spin yarns and dream of the time when they will have made their pile. On another shelf above the window is a bag of salt, several yeast powder cans, a paper of coffee, a couple of bottles of quicksilver, some plugs of tobacco, a worn pack of cards and a crib-board. In the corner is a bread pan, some molasses bottles, a demijohn and a pair of boots, under-

CORRESPONDENCE.

New York Capital in Mining.

(Letter from an Occasional Correspondent.)

NEW YORK, March 15th, 1873.

EDS. PRESS:—Since I have been here, in "the East," I have been struck with the surprising ignorance shown by New York capitalists in regard to mining interests. I happen to be in a good position for judging of this, and have been much interested in ascertaining, as far as possible, the actual feeling of the business community in the matter. I believe I am absolutely correct in affirming that the great majority of those who hold mining claims, with the intention of developing them, know next to nothing of their real, or even possible, value. Here is an instance of the mode of reasoning usually employed in reaching conclusions: A friend of mine, an excellent man of business in his own way, is badly afflicted with the mining fever. In speaking of the Great American Spread Eagle Gold, Silver, Quicksilver, Copper, Iron, Lead, Tin and Coal Mining Company (I may as well call it that as anything else; and, in truth, the name isn't so far out of the way), in which he has a large interest, he gave me the following, as an accurate summing up: "Paid for the original claim, \$75,000. Surveying and fees, \$8,000. Working expenses for first six months, (say) \$200,000. In two months will take out four hundred tons per week—call it two hundred, if you like. Assayed value of specimen gives \$7,485.72 per ton. Can't always depend on analysis giving a fair average yield, so we'll say half, or \$3,742.86 per ton. Total disbursements for the six months, \$283,000. Total income for four working months, \$11,977,152. Startle you, don't it? Well, we deduct nine-tenths, leaving a fair margin. That's \$1,197,715.20. Net profit, \$914,715.20, or over three hundred per cent in six months! Isn't it fair enough? Why I've divided the calculated amount by just 40, altogether."

Now, dear PRESS, you are doubtless used to this kind of talk in San Francisco. I remember it well enough. But what do you say to this? Another acquaintance, a photographer, showed me the other day a specimen he had been given to photograph by a "mining" friend. It really was a curiosity. A wad of dentists' foil well pounded and driven into a cleft of a piece of clear quartz!

These two stories look decidedly fishy, but they are of actual occurrence. Such things are heard of every day. If those who are personally interested in mining are so easily roped in, what can you expect from those who only hold stock for speculation, or never touch it at all? And the result. Can you wonder that, in this state of affairs, prudent men keep aloof altogether, and good opportunities go begging for want of capital? They cannot but see that the only parties who appear to make anything out of it are those who stake out the claims, and the well paid board of officers. It's like Santa Domingo—splendid thing to have a fat office in—but don't bite at the stock.

The problem of bringing about a clear understanding between miners, on the one side, and capitalists, on the other, is nearly as far from solution as ever. Men do not always see what is best for them, even millionaires; and if they will not—there's an end of it. Why, if European capitalists could only be brought to realize the difference between three-per-cent. and San Francisco real estate mortgages, we would all be so many pegs nearer the millenium. And the mining is on precisely the same footing. One investment is on a par with the other; for with our present knowledge and enlarged scientific basis, the mining of to-day is very different from the wild-cat-ism of old.

A. W., JR.

Hale & Norcross Mine.

The following items from the annual report of the Hale & Norcross mine for the past fiscal year shows a summary of the operations. The quantity of ore reduced compares as follows with previous years:

	Reduced.	Average.	Bullion.
1867, tons.....	28,636	\$47 32	\$1,355,220
1868.....	25,333	34 14	864,998
1869.....	16,330	23 69	395,146
1870.....	45,441	27 13	1,222,929
1871.....	64,974	25 13	1,638,844
1872.....	49,625	17 38	862,701
1873.....	40,417	16 28	657,950

During the past seven years this mine has turned out and reduced 270,962 tons of ore, varying in value from \$47.32 to \$16.23 per ton. The total out-turn of bullion during this period has been \$7,001,789, of which \$4,416,575 was in silver and the remainder in gold. From this large sum of \$7,000,000, stockholders ought to have realized something handsome. The fact is, only \$1,598,000 has been paid in dividends, while of this amount the Company have compelled stockholders to disgorge \$1,050,000 in assessments. The case may be stated thus:

	RECEIPTS.
Bullion product for seven years.....	\$7,001,789
Assessments seven years.....	1,050,000
Total.....	\$8,051,789

	DISBURSEMENTS.
Dividends seven years.....	\$1,598,000
Expenses seven years.....	6,400,675
Cash, February 28, 1873.....	53,114
Total.....	\$8,051,789

Deducting the assessments paid from the dividends received, we find the net profits to

stockholders to have been \$548,000, or a trifle over \$78,000 per annum, on an annual bullion product of \$1,000,000. Allowing the average capital employed to be \$1,000,000, the returns to stockholders show a small rate of interest. Of the 40,417 tons ore mined and reduced last year, yielding \$657,950, the sum of \$358,111 was paid for getting the ore to the mills and \$462,651 for reducing the ore to bullion. In other words, \$850,762 was paid to mine and mill a product of \$657,950. Under this view of the case, outsiders do not see where the profit comes in. Perhaps those who own and run mills for crushing ore can tell.

Deep Placer Mining.

Another of the series of free lectures at the Cooper Union, New York, was delivered on Saturday evening by Professor Silliman of Yale College, on "Deep Placer Mining in California." The following extracts are from the report of the New York Tribune: The lecturer introduced his subject by a description of the Ancient Geological Condition

of California as compared with that which now exists, showing how the gold region of the Sierra Nevada was reached, and remarking that all cañons in this country were formed ages ago by the action of running water, which left the heavy gold in small particles behind, in the crevices of the rock and the beds of the streams, by which men were able to get it by so simple a process as digging up the gravel and washing it out. In some portions of California there were areas where the deep lying gravels had been washed away so completely that all the gold was left behind, and as much as \$50,000 had fallen to the lot of a single "prospector" in a small area of perhaps 15 by 15 feet. But those things are only historic now; the days are past when men could pick up gold on the surface of California, and the primitive plan of "prospecting" with the pan was long ago superseded by more efficient methods.

He then described the various methods of mining in California, and the improvements that have been made. He then said: "But the most important step which has ever been made was the introduction of the hydraulic process, and there is an apparatus known as the 'knuckle-joint nozzle,' from which a stream of water six inches in diameter is projected against the face of the bank in an almost unbroken column with a force something like the discharge of ordnance." He then explained the nature and extent of the deposits, and referred to the remarkable phenomena of the

Table Mountains.

Which constitute a prominent feature of the gold region of numerous points from Oroville to Tuolumne. These Table Mountains were likened to the Palisades on the Hudson, being, like them, of volcanic origin, though of a much more recent geological age. They are, in fact, portions of the lava stream poured out so extensively during the great epoch of volcanic activity which closed the era of the ancient gravels in that portion of the world's history called by geologists the Pliocene. The speaker explained from diagrams upon the screen how these lava streams filled the valleys of

Ancient Rivers

Long before the alterations of the surface, due to subsequent denudation, which has had the effect of leaving this solid basalt unchanged almost completely, while the surface of the country surrounding has been cut down from 1,000 to 2,000 feet or more, by the valleys of existing rivers. The sagacity of the early explorers of the gold region of California detected the true nature of these remarkable dead rivers of the Pliocene time long before any hint had been given by the scientific world as to their nature. The adventurous and hardy miners undertook the exploration of these streams, now completely sealed over by the capping of hard basalt, by means of tunnels run in on the whole with remarkable skill, with a view to strike the ancient channel. These explorations were sometimes fruitful of remarkable results in the discovery of valuable deposits of the precious metals resting in the channels of the ancient river amid its sands and gravels and rounded boulders, mingled with the remains of ancient animals now extinct.

This Ancient Channel

Is at a depth sometimes of 300 or 400 feet beneath the level of the Table Mountain. This thickness is composed in part only of the ancient basalt, or lava streams, resting upon stratified deposits of volcanic sands and clays in the fine sedimentary portions of which are found the leaves of an ancient vegetation belonging to races of plants no longer found in California. Thus we reach the remarkable conclusion that what is now the elevated summit of the Table Mountains was formerly the depression of an ancient river, the valley of which, judging from the angle of the States, the upturned edges of which form the bed of the ancient stream, must have risen from 1,000 to 2,000 feet above the surface of the lava stream, thus proving that the general surface of the country has, subsequent to the outpouring of these Pliocene lavas, undergone a denudation amounting to not less than 3,000 to 4,000 feet of elevation.

From the consideration of the phenomena of the Table Mountains and the dead rivers which they entomb, the speaker passed rapidly to the discussion of the more

General Phenomena

Of the ancient rivers, the course and direction of which have been here and there detected in

the progress of exploration among the ancient auriferous gravels of the Sierra by the application of the hydraulic process. He illustrated this subject by a series of views thrown upon the screen, as well as by maps and sections showing the actual position of numerous points which have been well determined. Beginning in the high Sierras he illustrated and explained the great engineering works by which the waters of the melting snows are collected in artificial lakes and reservoirs for the feeding of the artificial canals or ditches, as they are commonly called in California, with the water, which is the essential element of success in this treatment of the auriferous gravels by the hydraulic process. Scenic views of portions of the deep-lying gravels, covered with primeval forests, as they are now seen in the headwaters of the South and Middle Yuba rivers, were also thrown upon the screen.

Placer Mining.

The speaker then mentioned in review the successive steps by which the precious metal is obtained from its resting place in the great mass of ancient alluvium. The upper portions of these gravels are always much poorer in gold than those which rest upon surface rock ("bed-rock.") The thickness of these auriferous gravels varies from 200 to 300 feet, up to nearly or quite 1,000 feet. The gold which they contain in the upper portions is sometimes not more than four or five cents in value to the cubic yard of gravel, and yet such is the power and economy of the hydraulic method that even this trifling quantity is profitably worked when the water and the gravel are both held in one ownership. As the upper portions of gravel are washed away the mass is found to become gradually more and more solid and compact, and changes in color from a red or tawny aspect, where it is sustained by the oxide of iron—changes by the influences of the atmosphere—until this color is replaced by the blue gravel which has given to the lower portions of this great mass the name by which it is familiarly known in California, as the "Great Blue Lead." As the "bed-rock" is approached the gravel mass becomes so compact that even the great force of the hydraulic washing is alone inadequate to break it up. Tunnels are then driven into the bank for a considerable distance, branches from which extend to the right and left, in which hundreds of kegs of gunpowder, and sometimes the gunpowder may be ignited simultaneously at numerous points by wires leading to an electric battery placed at a safe distance, after tamping the outlets securely to confine the explosion.

The lecturer proceeded to illustrate the several steps of the hydraulic process in the management of these great deep-lying gravels, which are destined to yield for an indefinite time in the future a steady and probably steadily increasing volume of the precious metals.

MAP OF LITTLE COTTONWOOD.—We learn from the Salt Lake Herald that Colonel Froiseth has finished his map of Little Cottonwood with its mining locations, and it was to be expressed last night for lithographing. It contains, distinctly shown, the twenty-one mines that have been surveyed for United States patents; some twenty tunnel locations, and about four hundred mining locations. Beside Little Cottonwood, including Alta and Central, and the numbers of their blocks as well as the names of the streets, it shows several of the more important portions of the Big Cottonwood district, and the mountain side leading up to American Fork district. This map is drawn on a scale of four hundred feet to the inch, from official surveys, and bears the indorsement of surveyor general Clements as to its correctness. When looking at it yesterday, and the large amount of careful work which it exhibited, the impression came strongly that it was one of the best things we had seen for conveying a correct impression of the mining region embraced, as it is, we think, decidedly the best map of the kind yet got up in this Territory. Colonel Froiseth writes us that the map is being engraved, and that it will shortly be placed on sale in this city. So much interest is being manifested in mining matters in Utah that the map will be very convenient for parties investing there or those who want to keep posted on the location of mines.

AGASSIZ MUSEUM.—Whatever may have been the result of the recent Hassler expedition, in which professor Agassiz embarked in scientific search of unknown denizens of the "vast deep," it is yet certain that from this voyage and others, contributions have flowed in from every source, and have given Harvard College the finest and most complete museum of "comparative zoology" in the world, in the specialty for which Professor Agassiz is famous. The collection of fishes is greater than that in the Jardin des Plantes, at Paris, and that in the British Museum put together. Professor Agassiz has devoted to it his life, and it will be his monument after death.

CINNABAR.—The San Luis Obispo Tribune says the Santa Lucia range from the San Simeon to the Arroyo Grande is rich in cinabar. Two mines of this mineral, situated near San Simeon, were recently sold to San Francisco capitalists. The Josephine mine, in the same range, and about twenty miles north of the town of San Luis Obispo, was opened several years ago, and upwards of \$100,000 have been expended in developing this mine. It is now yielding high grade ore, and manurea are in progress to erect additional furnaces. Discoveries of other deposits of cinabar have lately been made farther south in the range.

Manufactures of the United States.

It would be difficult, says the New York Journal of Commerce, to compress into smaller spaces the vast amount of useful information which appears in the tabular statement of the manufactures of the whole country. We have fortunately been enabled to obtain this highly important exhibit from advance sheets, in anticipation of this regular publishing day, about two weeks hence. Let no one be repelled by a chronic dislike of figures, from examining these remarkable statistics. This arrangement is simplicity itself. By a single glance across the line, one may trace the growth in manufactures of each State, between the decennial periods when the last three censuses were taken. Looking up or down the columns, he can instantly compare the development of any State, in this respect, with that of any other State; and be must be a dillard if the figures do not set him a-thinking on to the cause of the startling disparities he there finds. In point of suggestiveness—as key-notes to possible editorials, lectures and books—the tables are solid masses of text. We will not undertake to preach from them much to-day; but refer to this accompanying letter of our Washington correspondent for a few out of the many interesting deductions and moralizations which naturally arise from their perusal. To our mind, the most striking thought is this: What a terrific thing is civil war; how it blasts and cures the fair land over which it ranges! Here are the Northern States—led off by New York, Pennsylvania and Massachusetts, which always stood at the top in the order named—doubling or more than doubling the value of their manufactures between 1850 and '70; while the Southern States, nearly all of which exhibited large gains in this item of wealth between 1850 and '60, have made but small proportional advance in the last ten years, Virginia (including West Virginia), with all her recuperative energy, has gained but \$12,000,000 on her returns for 1860, whereas the census of that year showed an increase of \$21,000,000 over that of '50. Georgia is the only one of the distinctly Southern States which has doubled the value of her manufactured products, thus keeping pace with the average development of all the Northern States. All the other Southern States which staked their fortunes on secession, and were made to feel the sharpest effects of war, fall far behind the ratio of improvement which they would have shown had peace not been broken. Figures like these speak eloquently for peace—they are more potent than all the publications of the American Peace Society, the reports of their annual conventions thrown in. During the five years since the war (to 1870) the south would have made better headway in self-recovery had her disabilities been promptly removed and all the repressive measures toward her been discontinued. Material reasons combined with moral reasons in demanding that that act of justice and good policy should have been done long ago. Had it been done the Southern States would appear to much better advantage in the census of 1870 than they do; their citizens would feel more fully reconciled to a restored union, and the entire country would now be partaking, in abundant measure, of the rich blessing of peace. With these tables in view, we again press the claims of the South for immediate universal amnesty, in order that the least hindrance may be removed from her free natural growth. Let it be done, and we have no fear that the census of 1880 will not demonstrate the wisdom of that course in the great gain in southern manufacturing interests. Ohio, Indiana, Illinois, Iowa, Missouri, Minnesota, and all the thrifty States of the great West, though their chief wealth is agricultural, are yet highly prosperous, and waxing richer every day in manufactures. Nothing more forcibly exhibits their rapidity of growth in population and all that makes up civilized communities than the astounding leaps those States have taken in the manufacturing line in the past ten years. Iowa mounts up from \$14,000,000 to \$46,000,000; Michigan from \$32,000,000 to \$118,000,000; Minnesota from \$3,000,000 to \$25,000,000; Indiana from \$42,000,000 to \$108,000,000; Illinois from \$57,000,000 to \$205,000,000; Missouri from \$11,000,000 to \$206,000,000, and Ohio from \$121,000,000 to \$269,000,000. These illustrations are taken at random from the tables. The entire West—as well as the North—tells the same story of enormous gains in the value of manufactured industries of the past decade. All these figures, as a footnote apprises us, do not render full justice to the manufacturing industries of the country. For in the tables for 1850 and 1860 the statistics for mining, quarrying and fishing are included, whereas they do not appear in those of 1870. With this explanation the gain which we have pointed out becomes still more astonishing. Under a fully-restored union and fraternity, and a reformed Government, wise, just and economical, who can forecast the wonderful future of prosperity in store for the United States!

CAPITAL IN UTAH.—A dispatch from Utah says that letters from parties in London express much concern with regard to the management of Utah mines owned by them. It is stated that English capitalists are losing confidence, not as to the intrinsic value of the mines, but on account of the sharp speculative practices of parties interested in this Territory.

SCIENTIFIC PROGRESS.

Is Intellectual Labor a Transformation of Heat?

Brain work is accompanied by phenomena much the same as those attending manual labor. The tension of the brain, no less than the tension of the muscles, gives rise to heat, as may be ascertained without a thermometer. When a man is deeply intent on writing or thinking, his circulation grows more rapid; the arteries pulsate with increased force, and the brow is sometimes covered with perspiration; in short, it is clear that the nervous excitement under which he labors produces in his body a great amount of heat.

Are we to suppose that thought is the result of this development of heat, and that it will gain in force in proportion to the heat generated? We do not believe that any such relation subsists between heat and intellectual phenomena, and propose a physical interpretation for the increase of temperature accompanying cerebral action, which appears to be more rational.

The tension of the nervous system, and in particular of the brain, produces a kind of paralysis of the great sympathetic nerve. The functions of nutrition are retarded, but at the same time there occurs a dilatation of the blood vessels, and consequently an increased afflux of blood, which is diffused in great quantity through the entire system. The result is, a sufficiency of heat to facilitate the play of the organs; and then the mind is left free to give itself up to the subjects which engross it. The heat which is felt while the brain is active renders thinking easier, but has no part in the conception or creation of the works of the intellect.

This view of the increased circulation accompanying intellectual labor is confirmed by the results which we observe flowing from excessive brain work, namely: heaviness, trouble in the head, which can only be accounted for by a flow of blood to that region; then, in spite of this admonition one continues still to work, the consequence generally is cerebral congestion, or apoplexy, caused by protracted tension of the brain.—*Blondeau.*

CAUSE OF RUST IN IRON.—The study of that often-observed and unfortunate property which iron possesses of rusting or becoming oxidized when exposed to the action of moist air, has given rise to a variety of theories respecting this part that air and water each play in the operation. Mr. Von Hutton has made some experiments which lead him to conclude that the oxygen of the air cannot cause the rusting of iron unless dissolved in the water which is in contact with the iron. Even carbonic acid, when dissolved in water, will produce rust, which dry carbonic acid will not do. Rust, he thinks, is sometimes due to the decomposition of water, but that this never begins to take place until, for some other reason, the iron has begun to rust, or when the iron contains some other metal with which it forms a galvanic current. Solutions of alkalies prevent iron immersed in them from rusting, until the oxygen of the air dissolved in them penetrates to the iron, and this takes place more slowly in alkalies than with pure water. Alkaline solutions protect iron from the action of carbonic acid until all the alkali has been converted into a bicarbonate, and then if the solution takes up still more carbonic acid, it is able to attack the iron. The same authority, in discussing the protection of iron by contact with an electro-positive element, states that his observations have not shown any essential advantage to be gained in that matter.—*Sci. Am.*

ELECTRICITY.—When a rod of glass is rubbed with dry silk, vitreous or positive electricity is generated, which always flows to the north. When a rod of sealing wax is rubbed with dry flannel, resinous or negative electricity is produced, which always flows to the south. Then two kinds of electricity, though practically similar in capacity and character, are, nevertheless, opposite and mutually antagonistic in all their actions and effects. They combine, however, and harmoniously affiliate to establish an equilibrium between themselves, and they would forever exist in that state, if every other form of force was at rest. Friction upon glass, as we have already seen, evolves the one, and friction upon sealing wax evolves the other; but in neither case at the expense of either of the substances employed as a means of friction. The electricity is merely a conversion of the force employed into that agent. This is all that is known of the essence or origin of electricity.

CRYSTALLIZATION.—When evaporation takes place quietly in any saline solution, an active universal motion is perceptible, under the microscope, among the particles as soon as they become visible, as if each was endowed with life and intelligence. They act like so many animalcules or infinitesimal magnets. They repel and fly from each other in one direction and attract and attach themselves to one another in an opposite direction, finally assuming regular solid, geometrical forms. While attraction appears to be the basis of solidity, repulsion seems to assume a higher function, as if inspiring in matter a spirit of selection, adjustment and arrangement in certain specific orders of beauty.

PROCESS FOR EXTRACTING GOLD AND SILVER FROM COPPER PYRITES.—This method, invented by F. Claudet, is based upon the insolubility of the iodides of gold and silver. After the pyrites have been desulphurized by the addition of salt, they are placed in a barrel with a false bottom and lixiviated with acidulated water. The wash water consists of sulphate of soda, chloride of copper, and some chloride of silver. From this liquor the copper may be precipitated in a metallic state by means of sheet iron or iron scraps; but if the noble metals are to be separated, the waters from the three first extractions are collected, and the requisite quantity of iodide of potassium in solution is added to them. After having been left undisturbed for twenty-four hours, the clear liquor is drawn off, the vessel is then filled again, and iodide of potassium is added (in short, the operation is repeated) until a sufficiently large quantity of precipitate has collected. This contains sulphate of lead and copper salts, besides iodides of gold and silver. The salts of copper are washed out, whereupon the residue is mixed with zinc, in a finely divided form, which combines with the iodine. Hence the result is a mixture of gold, silver, lead, and some oxide of zinc, from which it is easy to separate the noble metals. Claudet produced in 1871, by this process, from 16,300 tons of desulphurized pyrites, 333,242 kilogrammes silver, and 3-172 kilogrammes gold, at a net profit of \$16,160.

REFINING GOLD BY CHLORINE GAS.—The application of chlorine to the refining of gold, as some of our readers may be aware, consists in passing a current of chlorine through the molten metal covered with borax. In a few minutes the silver present is converted into chloride, which floats on the surface, while the chlorides of lead, copper, antimony and arsenic escape. The fineness of the gold produced in this way varies from 991 to 997 in 1,000 parts; the few remaining thousandths parts of the product are silver, a quantity which is less than that resulting from any of the previously known processes. E. Dumas informs us that in the Mint in London as much as 750,000 kilogrammes of gold have been refined and toughened by the process, one kilogramme being 2,2046 lbs. avoirdupois. The apparatus is in use for only three days per month, and the cost of the chlorine gas is only from four to five francs for refining 5,000 kilogrammes of the gold. In order to refine 40 kilogrammes, a current of the gas for five minutes' time is sufficient. The silver is found in the borax covering the gold.—*Exr.*

NATURAL SULPHURIC ACID.—From a paper on the occurrence of native sulphuric acid in Eastern Texas, by J. U. Mallet, Ph. D., we learn that, not far from the Gulf of Mexico, and within twenty-five or thirty miles to the westward of the Neches river, there exist numerous small drainage-wells and shallow pools of water, strongly sour to the taste, this sourness being due to the presence of free sulphuric acid, which is accompanied by various salts, especially aluminum and iron sulphates. At most of these points gases are continually escaping, mainly hydrogen, sulphide and marsh gas, the bubbles burning readily on the application of a light. At the bottom of one of these ponds, known as Sour Lake, an earthy crust had been formed, in which free sulphur was observable. A thick, tarry variety of petroleum is also found oozing from the surrounding soil. The writer regards the occurrence together, in this region, of combustible gases, petroleum, sulphur, sulphuric acid and gypsum, as of great interest in its relation to the mineral history of native sulphur.

IMPROVEMENT IN THE MANUFACTURE OF SULPHURIC ACID.—M. de Hemptinne, a French manufacturing chemist, is said to have succeeded in establishing a new process for the concentration of sulphuric acid, by which it is claimed a great saving in cost is effected. Mr. H. states that the concentration of 100 kilogrammes, which costs 87 centimes by the platinum process, may, by his process (a vacuum method) be done for 44 centimes. He creates his vacuum by the condensation of steam in a cast iron boiler connected with a concentrating vessel of lead. The required strength of the leaden vessel to resist the atmospheric pressure is obtained by filling it with small irregular pieces of stone, such as will resist the action of the acid.

MEASURING THOUSANDTHS OF INCHES.—Nobody can take thousandths of inches from an ordinary scale; it requires an instrument with a Vernier, or a micrometer screw. You cannot even see the division of an inch in thousandths without a microscope. However, if you use this, you will have no difficulty in seeing not only thousandths, but ten thousandths of inches, with the greatest ease. Measures are ruled on glass, in which the inch is even divided in 100,000 parts, which is about the limit of the most powerful instrument. Such measures are called micrometers.

A NEW EXPERIMENT.—Mr. Elihu Thompson has made the observation that tin-foil, if wrapped about a few crystals of chlorate of potassa, can be made to detonate loudly upon being struck smartly with a hammer upon an anvil, or in a mortar. The phenomenon being precisely analogous to the well-known experiment of triturating sulphur and the chlorate. To the best of our knowledge, the observation that such metals as tin can be oxidized in this way, is a new one and worthy of notice.—*Jour. Fr. Institute.*

MATTER AND SPACE.—However vast space may be, matter must be circumscribed within it, like water within a lake. Hence matter is limited, while space is illimitable. Outside of matter is a limitless void—absolute space—nothing. Space is absolutely an illimitable void, within which suns, and planets, and moons push and pull, and rush and roll around each other, for the accomplishment of the wonderful ends for which they were created.

OZONIZED WATER.—A firm is at present engaged, in Berlin, in manufacturing ozonized water for medicinal purposes. From the prevailing opinion, which is not altogether without scientific probability, that the sanitary effects of sea air are to be ascribed to its relatively great proportion of ozone, the enterprise of the manufacturers will most likely be rewarded by a considerable demand for the substitute they claim to offer.

A THOUSAND DOLLAR PREMIUM has been offered by Uriah A. Boyden, Esq., of Boston, Mass., to be awarded to any resident of North America who shall determine by experiment whether rays of light and other physical rays, are or are not transmitted with a uniform velocity. The money has been deposited with the Franklin Institute.

MECHANICAL PROGRESS.

Effects of Magnetism Upon Iron and Steel.

It has long been known that both steel and iron were more or less structurally affected when under the influence of the magnetic current. One of Professor Tyndall's experiments shows the lengthening of a bar of soft iron whenever the circulation of an electric current round it causes it to take up the magnetic condition. Messrs. Treve and Chedeville have recently made experiments with a view to ascertain whether the influence of magnetism in any way alters the internal structure and tensile strength of cast steel.

They used two cylindrical moulds precisely alike, one of which was, however, in the center of a Ruhmkorff's coil charged by 12 Bunsen cells, while the other was left as usual. Both were filled with molten steel at the same time, and the electric current was allowed to circulate round the molten mass in the one mold until it was completely cool. At the expiration of ten hours the two steel cylinders were broken, and their fragments compared. It was then found that the grain of the metal differed very considerably in the two castings, being considerably finer in that subjected to magnetism during cooling. This experiment was repeated three times with the same result.

Comparative results were then made as to the resisting power of the two castings to extension and compression. In every case the strength of the magnetized steel was inferior to that of the unmagnetized.

Dr. Meyer of Hoboken, New Jersey, has also made experiments on the change in the dimensions of bars of steel and iron by magnetization. These experiments were performed with great care, with the aid of apparatus capable of detecting and measuring with precision a variation in length of one two-hundredth-thousandths of an inch. By means of this apparatus, he found that iron bars were elongated when a current of electricity was passed around them; when the current was interrupted, the bar shortened somewhat, but never again regained its original length. With annealed steel bars the result was the same; but with tempered steel, the results were altogether different. On passing the current around these they contracted, and on interrupting the current they contracted still further.

He also made some experiments to determine whether there was any change in volume in a hollow cylinder of iron when it was magnetized. For this purpose a hollow cylinder, closed water-tight with the exception of an opening in the upper cup, into which a glass tube with a fine bore was fixed, was filled with water so that the water stood in the glass tube some distance above the top of the cap. On passing a current of electricity around the cylinder, the water sank in the tube, showing that the capacity of the cylinder was increased. Other experiments showed that when a bar of iron was magnetized, an increase of temperature took place. This was beautifully shown by the above experiment, when contact was made and broken several times; the water in the cylinder was so heated that it overflowed the top of the glass tube.

STEEL RAILS.—Last month the large rolling mill of the Philadelphia & Reading Railroad Company in Reading, Pa., made the first steel rail ever manufactured in that city. The steel was obtained from the Midvale Steel Works, at Nicetown, near Philadelphia, and is of the Siemens-Martin process, and was furnished to the rolling mill in the shape of ingots of about nine inches square, in sections, and the rails were rolled into the ordinary pattern of sixty-eight pounds per yard. It is expected they will be as durable as any Bessemer steel rails made.

Railway Brakes.

The business of manufacturing railway brakes is much more important than is generally imagined. Seven companies for the manufacture of power brakes have been organized in the United States since 1869. And of the 444 railroads in the United States and Canada, more than one-sixth of them have already been equipped with power brakes operated by the engineers.

In England, from 1840 to 1866, there were patented twenty-two electric brakes; from 1835 to 1865, twenty hydrostatic brakes; thirty pneumatic brakes from 1838 to 1866, and fifty-four steam brakes from the year 1836 to 1866.

Power brakes, operated from the locomotive, are a very old invention, although they were never adopted by any railroad company in the United States until about three or four years ago.

The first power brake patent granted in this country was in 1847, and the total number granted up to the close of last year was fifty-nine. More patent on power brakes were granted in 1872 than from the organization of our Patent Office to the close of 1871, which strikingly illustrates the rivalry of the inventive genius of this country.

At a recent trial of a power brake on the Chicago and Northwestern railroad, a train of six cars, going at the rate of thirty-two miles an hour, was stopped in 19 seconds; the same train, going forty miles an hour, was stopped in 18 seconds, and within the space of 370 feet. The time in which to stop a railroad train is the all-important consideration. It surely would take three minutes to stop a train going at this speed with the ordinary hand brakes. A minute in railroading is sometimes a very important matter.

A bill was introduced in the House of Representatives to compel all railway companies to provide their cars with power brakes, so arranged that the engineer may, at any moment, apply power to the wheels of every car on the train. Penalties are provided against companies who fail to employ some kind of an approved power brake.

To Determine the Dimensions of Fly Wheels.

The rule given by Molesworth for weight of fly wheel rim is as follows: Multiply the average pressure on the piston, in pounds, by the length of stroke in feet and divide by 45 times the diameter of the wheel rim. The result will be the weight of the rim in hundredweights. To obtain the weight in pounds, multiply by 25 instead of dividing by 45. Haswell says that the weight of the rim should be from 85 to 95 pounds per indicated horse-power of the engine. Professor Thurston gives the following memorandum: The effect of a fly wheel will depend upon the proportion which the product of the weight into the square of the velocity of its rim bears to the quantity of work which is alternately stored up in it, and restored by it. The latter quantity will vary with the length of stroke of the engine, the size of its cylinder, the pressure of steam carried, and the point of cut-off. It would be difficult to construct an exact formula that would be adapted for general use, but the following rule will give good results with our best forms of engine with considerable expansion: Multiply together the area of the piston, in inches, length of stroke, in feet, and highest proposed steam pressure; divide the product by the square of the product of the diameter of the wheel, in feet, by its lowest proposed number of revolutions per minute. Finally multiply the result by 90,000.

This formula was first proposed in 1867, and has given satisfactory results. Its author prefers it, for ordinary purposes, to any other published.

To determine the sectional area of the rim from its weight, divide the given weight by ten times the diameter in feet, and the result will be very exactly the cross section of the rim in square inches.

It is, of course, better to make a fly wheel a little too heavy than a little too light, while a perfect regularity of speed is of very great importance.

SLATE ROOFING.—An item has been extensively circulated concerning the advantage of bedding roofing slate in hydraulic cement, over the usual method of nailing them on dry, which leaves them subject to be rattled by the wind, and be readily broken by accidental pressure. The cement soon settles and becomes like a solid wall. The additional cost of the plan is 10 to 15 per cent., but this, in virtue of the increased permanency claimed for the new plan, may really place a saving to its credit, in addition to which the greater security it affords against fire is a point in its favor.

AN IMPROVED CASK.—A Mr. Trimmer has recently invented a cask, which consists in making one or both ends partly or entirely of glass, so that the observer may see whether it is full when delivered, when it has become sufficiently empty to replace it with a fresh one, at what rate its contents are being reduced, and also when empty, whether the cask has been properly cleaned. The inventor in some cases, uses a cask head made entirely of glass, and in others a strip of glass let in vertically or diagonally, and properly secured from leakage.

Assessments, Meetings, Dividends.

NOTE.—In the Stock Boards an assessment is delinquent thirty days from the date of levy, exclusive of that date. The dates given in this list are those of the running offices.

Gould & Curry. Letter of the 24th says they have not reached the quartz with the east drift, on the tenth station. Have run 25 feet during the past week. On the north drift, on this level, have made 17 feet; still in hard blasting rock. Putting down the pumps in the incline. Hope to commence sinking again in about three weeks.

Hale & Norcross.

Weekly report for the week ending on the 22d gives the following summary of operations: Ore extracted during the week, 1,234 tons 1,500 pounds; forwarded to the mill, 863 tons 860 pounds; on hand at the dumps, 1,055 tons 750 pounds. The ore came from the following sections of the mine: Lower mine, first station

Mining stocks have this week been at a discount. There have been few sales, and what have been made were at paucic prices. Leading operators look for a change in this state of affairs very shortly, but they have been expecting it for some time to no purpose. A rich strike on the Comstock would, however, very probably cause a reaction and send prices up again. Last Monday, under the rule of the Board, sales for account were, for the first time, auctioned by the Caller, all persons not members of the Board being allowed to bid as well as members, the buyer to put up 20 per cent. immediately. The public, not being aware of the new arrangement, were not prepared to bid, and only a few sales were made. The increased number of shares being offered, and the stringency of the money market are said to be the causes for this depression in stocks, for the mines are doing as well as they were when stocks were so high last year. Some heavy operators have withdrawn from the market for the present, and that helps to depress it to a considerable extent.

On Saturday they were irregular and weak, most descriptions showing a decline. Chollar-Potosi and Consolidated Virginia each advanced \$3, Belcher, Ophir and Raymond & Ely each \$1. Alpha and Segregated Belcher each declined \$3, Caledonia, Golden Charlotte & Norcross, Mahogany, Overman and Savage each \$1.

Tuesday the decline still kept on with no orders to buy in the market. At close Yellow Jacket and Savage were each \$1 higher; Hermes rose \$3; Raymond & Ely fell \$3; Chollar, \$3.60; Belcher, \$3.50; Cons. Virginia, Uerman and Gold & Curry each fell \$1.

Wednesday there was no improvement in prices or in business either at the morning or afternoon board. Whollar fell \$4; Cons. Virginia, \$2; Hale & Norcross, \$2; Meadow Valley, \$1; Raymond & Ely, \$5; Savage, \$1; Yellow Jacket, \$1.

To-day there were but few changes of interest in stocks. Belcher, Overman, Segregated Belcher and Yellow Jacket were each \$1 higher than yesterday noon. Chollar Estate and Cuban each declined 50 Cents. IF

The following items from prominent mines are taken from letters or dispatches from the respective Superintendents, which are on file in the offices in this city:

American Flag.
Superintendent's letter of the 19th says the main shaft is down below the fifth station 37

Amador Tunnel.
Dispatch dated the 26th reports pulp assays at \$180.

Belcher.
Dispatch of the 26th says the south crosscut does not look quite so well as usual. Stopes look well. Car samples, \$52 per ton.

Chollar-Potosi.
During the week ending on the 22d 387 tons of ore were taken from the main, and 262 tons 100 pounds sent to the mills. Average assay value of ore mined, as determined from car samples, \$40 20. Ore slips 20th and 21st, 124 tons 1950 pounds.

1900 pounds.

Con. Virginia.

Letter of the 23d says that the work of sinking the main shaft is progressing very favorably, its advancement downward being at the rate of 3½ feet per day. Have crosscut the ore vein at a point 55 feet south of the north drift, which shows a width of ore of 28½ feet. The quality of the ore exposed by this crosscut is better than that passed through in the north drift. No ore is being extracted except that taken from the north drift, and no ore has been shipped for reduction.

Crown Point.
Letter of the 22d says they have shipped to the various mills during the month, so far, 10,313 tons 540 lbs of ore; that will, estimating it at 65 per cent of the pure metal, amount to 6,703 tons.

per cent of the assay value, amount in the aggregate to \$653,909.19.

Dispatch of the 24th says they have struck the east wall in the north drift from the main east crosscut on the 1300-foot level. The ore is good clear up to the wall. This drift runs

east of north, following the course of the vein. The 1300-foot level floors are all looking very finely. The incline is down 109 feet in hard blasting ground. There is no change elsewhere in the mine. The amount of hullion received at the San Francisco office for the month up to the 22d was \$402,556 17; received on the 24th, \$63,807 80—making the total for the month, so far, \$466,363 97.

Dispatch of the 26th says there is no material change in the mine since the last report. Put in the new incline rope yesterday, without delaying the mills. The ore breasts look well as usual, and everything in and about the mine

Eureka, Grass Valley.
Letter of the 22d says the clean-up for the last

six days run of ten stamp, was 1,500 ounces of amalgam. The bottom west drift shows a little water, and the ground is a little harder. No change in the east drift. The ledge in the sixth level raise is three feet wide, and the quartz looks well. The ledge in the intermediate drift and stopes looks well. Everything is running well, with no change in any other part of the mine.

level, 8 tons; second station level, 609 tons, 1,500 pounds; ninth station level, 350 tons; tenth station level, 237 tons; twelfth station level, 30 tons. Work at the mine is progressing favorably.

Huhn & Hunt.

Dispatch of the 25th says the ore from the back and front ledges is mixed, and the pulp assay gives from \$39 to \$32 per ton. All ore

east from Pioche, are very encouraging. Machinery is now on the road from Salt Lake for hoisting works and a 20-stamp mill.

The Spectroscope—An Interesting Lecture.

Prof. Neri introduced his third lecture on spectrum analysis by remarking that, as his audience had already, by previous lectures, mastered the principles upon which spectrum analysis is founded, he would now approach

The Method of Its Application.

A fine spectroscope was introduced to the audience, and the principles of its construction and connected appliances were fully explained in detail, and also the successive steps and discoveries by which it has been brought to its present wonderful state of perfection. The analysis of light by the prism as discovered by Newton, 200 years ago, laid the foundation of spectrum analysis. But Newton made his observations by receiving the rays of the sun through a round hole—a method which never would have led to the discovery of the spectroscope. Hence the next important step was not made until 1852, when Wallaston used a *slit* instead of a round hole to receive the rays. The subsequent introduction of the collimating lens, by Mr. Sims, in 1830, by which the rays were properly collected in parallel lines before the observer rendered the spectroscope an instrument of practical value; and finally the introduction of the telescope, as an adjunct, still further perfected it, and rendered possible the magnificent results obtained by Bunsen and Kirchhoff in 1860 and '61. The very latest introduction is the micrometer scale, by which the observer is able to fix accurately the position of the bands of light within even a small fraction of a second of time—as must necessarily be the case in obtaining the spectrum of a flash of lightning. The spectroscope, together with the micrometer, was projected upon the screen by the use of a magic lantern and the electric light, so that it could be readily explained to the entire audience.

Sir Charles Wheatston, in 1835, was the first to distinguish metals by their different colored spectra, and it is considered the greatest triumph of the spectroscope that four new metals—rubidium, caesium, thallium and indium—were discovered by that instrument within the space of four years. Since the spectroscope became of practical value, the progress in science and the arts has made most wonderful progress—an advance largely due to the results of this wonderful instrument.

In order to give a practical demonstration of the use and operation of the spectroscope the lecturer caused various metals to be burned in a voltaic arc, in such a manner as to throw their spectra upon the screen, when the manner in which the various colors of the metals under examination were brought out, was beautifully apparent to every member of the large audience present. It was thus made apparent why all substances examined by the spectroscope must be in a vaporized condition before they can be analyzed by that instrument, that is before the light which they emit can be divided up into its distinct colors so as to fall into their proper places on the spectrum.

When a solid body is simply heated to a luminous point, say to a red heat, so as to give off light, without vaporization, the light is not divided into component colors; but falls upon the screen in what is termed a continuous spectrum—that is, a spectrum made up of all the components of the light exhibited in a combined state, like sun-light when not separated by a prism. In such a condition light cannot be analyzed, and, of course, we can tell but little of the nature of the body so emitting its light.

Hence the spectroscope readily reveals to us whether a luminous body—a star, a comet, a planet, or any highly heated earthly substance—submitted to it is solid or gaseous. Of course a solid body surrounded by a gaseous atmosphere, or giving off volumes of gas would be reported *gaseous*. These are very important facts in connection with the application of spectroscopic examinations of the heavenly bodies. It is an important and well-ascertained fact that no two vaporized substances ever give off lines corresponding in number, color and location on the spectrum. Hence no one substance need ever be taken for another, when submitted to the spectrum.

The Spectroscope Applied to the Industrial Arts.

As illustrative of the manner in which the spectroscope is applied to the industrial arts, a view of a Bessemer steel converter was thrown upon the screen, and the method was explained

how the very instant when cast iron was converted to steel, was distinctly and intelligently shown to the audience. Without the use of this instrument such knowledge could only be (and even then imperfectly) acquired by years of practice and perhaps at the cost of spoiling many tons of iron. Thus it is by the spectroscope only that this, one of the most important inventions of the age has been rendered complete and perfect in its operation.

The Spectroscope Utilized upon Dark Substances.

The lecturer next proceeded to show how the spectroscope could be made useful in detecting adulterations in common articles of food, of wine, etc., to determine the presence of poisons in blood.

This was accomplished by the principle of the *absorption* rather than by the emission or analysis of light. If a small quantity of cheese or butter, or any similar substance was dissolved in some menstruum like ether, and ordinary light passed through it, that light would be more or less absorbed by the substances present, the amount of which absorption may be known, and the agent causing it detected.

The presence of an infinitesimal portion of carbonic acid in blood could thus be detected, although there might not be one-thousandth part of a grain of blood submitted to the test, so delicate and absolutely perfect is the instrument.

One of the most delicate and beautiful experiments was introduced as the closing one, showing that the spectroscope possessed the property of bringing out the phosphorescent properties of bodies. It was possible, for instance, thereby to unerringly detect a false from a genuine diamond—as the genuine diamond is phosphorescent, yet almost imperceptible to ordinary vision, while no imitation, either of paste or quartz, possesses that property.

This was decidedly the most interesting lecture of the series, thus far, and was illustrated by a great number of experiments to which we have not the time to allude at all. The best evidence of the estimation in which it was held is the fact, that so many people could be kept together under the most intense and absorbing interest until past 11 o'clock. The next lecture of the course will be given on Thursday evening, April 3d.

The Age of Steel.

The remarkable progress in the manufacture of steel bids fair to be equalled by the rapid production of cast-steel castings, adapted to many uses where iron is now wholly employed. The first attempt to make a plowshare from the crucibles was a failure. This can no longer be said, for the Pittsburg Steel Works Company, of which J. G. Kittredge & Co., of this city, are agents, are now manufacturing all kinds of heavy cog-wheels, cast true to the pitch-line, showing sharper courses, and said to be in every respect equal to the best iron castings ever made.

When subjected to severe tests from hammers, which would shatter iron wheels of similar dimensions, these were unscathed. At their works they also manufacture light articles, such as six-ounce wrenches, which, when taken from the moulds, are as clean and sharp as malleable iron castings; the number and character of light castings is without limit. They guarantee the pick manufactured by them to stand more service than any thing in the market, and also pay special attention to the manufacture of steel shoes and dies for quartz crushing. From the certificates shown us from several mills where they have been tested on this Coast, they appear to give entire satisfaction. At the low prices at which these castings are furnished, they must be of benefit to the mining interest, for anything which tends to reduce the cost of reduction of ores will be in great demand on this Coast.

When the cost of freight is taken into consideration together with the saving of time in changing shoes and dies, and the length of time the steel ones wear, the difference in them will no doubt be very great. It is claimed that the steel shoes and dies have a greater crushing capacity as they always maintain a full surface.

CAMELS PACKING WOOD.—It is stated that in Virginia City the camels are engaged in packing wood to the Gould & Curry works. Their labors are performed at night, as the authorities forbid their appearance on the streets in the day time, in consequence of the terror their appearance excites among the horses.

The Suto Tunnel of Pioche District—The Pacific.

On the lower foot-hills southeast of Pioche, and a few yards north of the old Ely smelting works, is the mouth of the celebrated Pacific tunnel. Its location is not far above the average level of Dry Valley, which is rimmed on the east and south by the mineral hills it penetrates—it being only high enough above the main basin to insure continuous dumping facilities. The general course of the tunnel is southerly.

The great enterprise was commenced in 1870 by S. R. Nichols and H. C. Church, two miners whose energy and practical judgment are acknowledged by all. The task must have appeared Herculean to these enterprising gentlemen, as they stood on the initial point of the proposed tunnel and viewed before and above them the mighty hill of upheaved quartzite, with its main vein-lines of mineral hundreds of feet away to the east and west. But the developments above proved that deposits worth millions would be tapped by driving right in, and it was resolved that the great enterprise should be undertaken. The mouth of the tunnel was accordingly marked out, 6 ft. 6 inches high and 5 ft. wide, and the work was inaugurated. Day and night the excavation of the solid quartzite was continued, each foot gained in length being several feet gained in vertical depth from the surface, until the 480th foot was attained, and a rich mineral vein exposed 4 feet in width, with regular dip and well-defined walls.

Then the value and practicability of the enterprise were admitted by all, and capitalists at home and abroad stood ready to invest in it. Above and running at right angles with the tunnel were some of the richest veins of Ely Mining District, and all tending downwards in the same general direction, irresistibly leading to the conclusion that at a point below the line of surface disturbance they all emerge into one mighty chamber of argentiferous wealth. A company was incorporated without the slightest difficulty, and it was determined to continue the tunnel right into the heart of Spring Mountain and the center of the great silver deposits which have already swelled the coinage of the world at least ten millions, and the developments of which has scarcely commenced.

So night and day, the great enterprise was pushed ahead until 575 feet more were excavated, making 1,055 feet from the mouth of the tunnel, when a vast body of talcose slate was encountered, interspersed with mineral matter. Progress continued a few feet further through this talc when another rich vein of ore was exposed, being four feet in width and assaying up to the standard of the highest grade ores. At this point it is instrumentally demonstrated that the American Flag Company are extracting their richest ores only fifty feet distant. We turn and retrace our steps half the distance to the mouth of tunnel, where miners are distinctly heard carrying on their developments in the Mariou mine.

The last vein cut, or vein No. 2, goes down almost vertically, and seems to be widening as it descends. The ores are carbonate in character, intermixed extensively with chlorides. But as rich and extensive as this vein is, the company will not be diverted from their original purpose of going into the very heart of Spring Mountain, and far below existing developments, before giving special attention to bullion production. Within the next six months the tunnel will have been driven in at least 1,500 feet, when the greatest veins of the district will have been out by it at points far below the possibility of surface developments reaching for years. Future operations will be watched with deep interest, as they will probably give the world the first practical demonstration of the permanency of our mines. The tunnel will be extended beyond the Huhn & Hunt mines—the highest developments on Spring Mountain—before the management will think of suspending operations. It will soon cross the Standard, Bowery, American Flag and Sunbeam ledges, but beyond the lines of their locations, so there will be no probability of ensuing litigation.

The work on the Pacific Tunnel is being done in the most workmanlike and substantial manner, strongly and durably timbered wherever needed, and it will stand for generations a monument of the energy and bold enterprise of its projectors; and we feel safe in saying that the time is not distant when millions of dollars worth of rich ores will pass through it. It would be valuable property without the rich mines intersected by it, as three or four of our leading mines could reach it by cross drifts, and at comparatively trifling cost.

This great enterprise may properly be termed the Suto tunnel of Lincoln county. — *Pioche Record.*

ARIZONA COLONY.—The *Paria American Register* says that some American and French contractors and bankers in Paris have procured land in Arizona, where they intend to establish a French colony and also to construct a rail road from the port of Guaymas, on the Gulf of California, to Fort Mohave, in Arizona.

WORK AT VIRGINIA CITY.—There are many miners and mill hands out of work in Virginia City at the present time. One foreman says it is "with the men as with fleas—when one gets a place it brings forty more." The horse disease has had much to do with this state of affairs.

Utah Mining Matters.

We glean the following item from an article on the "Resources of Utah" in the Salt Lake Tribune:

General Review and Future Prospects.

The coming season appears to be unusually bright for the Territory from a business point of view, indeed the outlook was never so bright as now, and it is safe to predict that the present dull state of business affairs will be followed by a reaction that will gladden the hearts of many who are now despondent.

In mining matters the prospects surpass those of any past season, and developments in every district proving the existence of most valuable mines, while English, Foreign and Eastern capital is better disposed toward Utah than formerly, and the probabilities are that, early in the season, capitalists will not be slow to invest in mining property offering good inducements.

Railroad building this season has assumed gigantic proportions, hundreds of miles of narrow-gauge roads being in contemplation with every prospect that work will be pushed with extraordinary vigor. Necessity for rapid communication with all parts of the Territory is apparent to every one conversant with our resources and their rapid development. The early completion of a road to Pioche is imperatively demanded in the interests of our merchants, while several short roads to the various mining camps are scarcely less necessary. Not only will our own roads vitalize the Territory with the money expended in their construction, but those now contemplated in southeastern Nevada—the road from Pioche to the Colorado, and others centering here—will also exercise an important influence on the growth and prosperity of Utah. In this connection we again call attention to the great iron and coal interests in the south, and hope that the manufacture of iron on a large scale and shipment of coal to points in the West will be accomplished during the year.

The erection of quartz mills and smelting works in various parts of the Territory will undoubtedly make available large amounts of ore now awaiting treatment at points from whence it will not pay to ship in a crude state, and will otherwise do much towards creating new points for business.

Capital and Capitalists Coming.

Reports from England are more favorable than lately in relation to American mines, and confidence in their being paying investments seems to be gaining ground rapidly.

The Hollanders have, through agents here, been investigating our mines, and are showing their appreciation by making purchases of mining property. An agent of parties in Frankfurt recently left the Territory for his home, and assured us that he was perfectly satisfied with the result of his investigations, and that he should advise his friends to invest their capital in such valuable property.

We also learn from reliable sources that some wealthy men from Michigan design erecting extensive smelting works on a large scale, and at a heavy expense, near the south end of Great Salt Lake.

We understand the intention is to reduce the ores from the Utah Queen, Converse and Miami mines. Much as Michigan has been interested in Utah mines during the past year, it is expected that the Peninsular State will invest much more in this Territory during the coming season.

The attention of men of influence and capital in St. Louis, Missouri and Cincinnati, and Cleveland, Ohio, has of late been drawn to a consideration of the benefits to be derived from the investment of their money in our mining and manufacturing interests.

Discovery of Gypsum.

A large bed of this valuable material has recently been found about 100 miles west of Cheyenne. The specimen exhibited by the discoverer, Mr. Charles Amee, is of very fine quality and indicates a high commercial value attached to the discovery.

Hematite Ore.

The Rocky Mountain Vermillion Paint Works of Rawlins, Wyoming Territory, are supplying hematite ore for fluxes at a much lower rate than the article has heretofore been offered to our smelters. The price is only three dollars per ton on board of the cars at Rawlins.

New Coal Mines.

Coal has been discovered in Spanish Fork cañon, eighteen miles from the settlement. The specimens taken out are excellent. The extent of the deposit has not yet been ascertained, but those at work upon it are of the opinion that a large body of coal will soon be reached.

A report is also current that coal has been discovered in Box Elder cañon by persons living in Brigham City, but the report requires confirmation.

The Production of Lead.

No feature in the future of this Territory presents itself to our minds charged with such lasting benefits in a commercial point of view as the utilization of our argentiferous resources; for their development will form a source of wealth, at some future day, the value of which cannot be over estimated. The manufacture of pig, sheet, bar, shot and white lead will, we predict, be not only one of the leading branches of industry, but rank among the chief exports of this Territory.

USEFUL INFORMATION.

VALUE OF SWEEPINGS.—It is stated that one of the jewelry manufacturers in Newark, N. J., recently put down a flooring in their workshop, and that the gold they obtained in burning the old flooring not only paid for the new one but for putting two coats of paint on the entire factory. In another the hands all work on a sort of bracket standing out from the bench in front of them, so that the filings of gold may fall on a tin plate below, and be returned to the melting-room. The greatest care is exercised to prevent waste. The floors, benches and seats are carefully swept every evening, and the sweepings put away to have the gold removed from them by chemical process. Every now and then aprons, benches, stools, and even the flooring, are burnt up to get the gold out of them. Even brushes, clothes, cotton, wool and rags are burned. The average quantity of gold saved annually in this way in this factory is about \$50,000 worth. All the water in which the 500 employees wash their hands is carefully filtered four times, and the amount of gold recovered from it averages about \$15,000 a year. A barrel of sweepings will fetch \$4.50 a pound; and even after they have, as they think, extracted all the gold from them, they sell the refuse to the smelters at nine cents, and even as high as eleven cents a pound.

GREEN VARNISH.—There is a most beautiful transparent green varnish employed to give a fine glittering color to gilt or other decorated works. As the preparation of this varnish is very little known, an account of it may in all probability prove of interest to many of our readers. The process is as follows: Grind a small quantity of a peculiar pigment, called "Chinese blue," along with about double the quantity of finely powdered chromate of potash, and a sufficient quantity of copal varnish thinned with turpentine. The mixture requires the most elaborate grinding or incorporating of its ingredients, otherwise it will not be transparent, and therefore useless for the purpose for which it is intended. The "tone" of color may be varied by an alteration in the proportion of the ingredient: a preponderance of chromate of potash causes a yellowish shade in the green, as might have been expected, and *vice versa* with the blue under the same circumstances. This colored varnish will produce a very striking effect to japanned goods, paper hangings, etc., and can be made at a very cheap rate.—*Cabinet Maker.*

TO PRESERVE BOOKS.—It is not, perhaps, so generally known as it deserves to be, that a few drops of any kind of perfumed oil will secure books and manuscripts from the deteriorating effects of mold and damp. The species of leather so extensively used by book-binders owes its powers of withstanding the effects of these destructive agents, to the tur of the birch tree—*Betula alba*. The preserving of books, written on papyrus and parchment, by means of perfumed oils, was known to the ancients. The Romans made use, for this purpose, of the oil of cedar; hence, undoubtedly, the expression of Horace, "*digna cedra*," meaning any work deserving of being anointed with this oil.

POPULAR FALLACIES.—One of the most singular things is the tenacity with which popular fallacies cling to existence. Thus almost every man you meet believes that hairs are tubes, although this has been disproved over and over again by taking a hair and examining a cross section under the microscope. So too, most persons believe that every drop of water is filled with animalcules, while the truth is, that microscopists find it difficult to get specimens of water that contain enough for examination. It is true that some of the water supplied to our large cities will exhibit an abundance of animal life without the use of the microscope, but good well-water contains very few animalcules.

VARIETY IN COLORS.—New tints of the various colors are constantly being discovered. Over 2,000 established shades have already been produced for the dyer's art, and the number is constantly increasing. Among the forty or more shades of blue, scarlet, crimson and yellow, there are hues which were wholly unknown a few years ago, and for which it has been necessary to coin an arbitrary name, as they resemble nothing previously known. Every little while the popular fancy demands a new variation, and colors must be mixed and blended until something entirely novel is produced. It may be pretty or otherwise—that is regarded of comparatively little importance, provided it is the style.

ELASTICITY OF SPONGE.—Ordinary sponge out into small pieces and submitted to certain chemical processes, acquires such remarkable elastic property, that a weight weighing but one pound, compressed into a space of three inches in thickness by six in length and four in width, when cut apart, will expand to over two feet in length.

COLD AS A FOOD PRESERVER.—M. Boussingault recently mentioned the fact that a number of samples of soup, meats, etc., which had been kept since 1865 in closed vessels at a temperature of 20°, retained all of their original qualities. The author also mentioned that the fact was true of the juice of the sugar cane kept in a similar manner.

A SUBSTITUTE FOR IVORY.—An exchange says that a manufactory has been started in Newton, New Jersey, for making an article out of gum camphor and other materials, which is destined eventually to supersede the use of ivory. By this process the coming substitute for ivory can be heated and moulded into any shape or form desired. A practical substitute for ivory has long been an important desideratum.

A HUNDRED YEARS AGO.—The first stage coach from New York to Boston started on the 24th of June, 1772, from the "Fresh Water." It was to leave each terminus once a fortnight. The fare was four pence, New York currency, per mile. It reached Hartford, Conn., in two days, and Boston in two more. The proprietors promised a weekly stage "If encouraged in their great enterprise."

SINGULAR CHEMICAL TRANSFORMATION.—A sheet of ordinary white blotting paper which will tear by its own weight when wetted, is converted into a material having all the properties of a tough parchment by merely dipping it for a few seconds into sulphuric acid. The Germans are using this artificial parchment for sausage skins. It need hardly be said that it is highly indigestible.

STOPPING RUNAWAY HORSES.—Among the patented contrivances for stopping runaway horses, one consists of a pair of nose stoppers, attached to a bit, which are closed over the nostrils of the animal by means of a cord, which the driver pulls if the horse attempts to run. Another consists of a pair of blinders, by which the driver, on pulling a cord, instantly blindfolds the animal.

NOVEL MODE OF MEASURING THE HEIGHT OF TREES.—The Canadian way of measuring a tree is said to be as certain as it is grotesque. You walk from the tree, looking at it from time to time between your knees. When you are able to see the top of a tree in this way your distance from the root of the tree equals its height.

CHINESE LABOR.—Employing cheap Chinese labor is not always the best thing in the world for the interests of the manufacturers. In many cases no sooner do they learn the art of making the things, principally hoots and shoes, and cigars, so far, than they turn and set up for themselves, selling at much lower rates.

A FORTUNE FROM LAMP CHIMNEYS.—A glass blower of Pittsburgh, Pa., was the original inventor of lamp chimneys, and has realized over half a million of dollars from his invention.

FROM JOPPA TO JERUSALEM BY RAIL.—Cars now run from Joppa to Jerusalem in two hours.

GOOD HEALTH.

Sanitary Conditions.

Dr. T. M. Logan, of Sacramento, delivered a lecture before the Polytechnic class last week on the subject of California Meteorology and Sanitary Condition. Dr. Logan commenced his remarks by explaining that he did not lecture last week, as announced, because of a misunderstanding—the committee failing to notify him of the change of programme.

The carefully prepared lecture was mainly devoted to hygiene, and addressed more to unprofessional than professional ears. The lecturer adverted upon the uniformity of animated nature in the primeval ages, and the failure of such uniformity with the present occupants of the various countries of the globe. The study of ancient history and literature, he was inclined to think, was too much neglected.

Laws of Health Governing the Ancients.

In the most ancient ages laws of health were associated with the laws of government. These laws date from before the time of Moses, which is proved by temples devoted to hygiene. In Greece, sanitary laws were most carefully observed. By wholesome sanitary laws Sparta created an iron race of men, but more for warlike purposes than social happiness. In Athens symmetry of form was more thought of than robustness. Rome carried sanitary laws to a greater perfection than had before been known, and the proof of their success was the superior power of the Roman legions. The collections obtained from ruins show that the rules of health were very radical. From the decline of Rome less attention was paid to these laws, and the result was a rapid accumulation of all diseases affecting the human race. Enlightenment has increased the average of human life from twenty to forty years. In Turkey the laws requiring ablution are worthy of higher civilization. Since the destruction of Rome by Northern barbarians, and the people became slaves of a priesthood, the broad domains have become sickly marshes, and the people no longer obey the laws of health. Unless something is done, history will repeat itself, and the same fate will befall the fair lands of our Southern States.

Ravages of the Plague.

The lecturer quoted historical accounts of great plagues which had swept over Europe. In the fourteenth century the black death carried off one-quarter of the population of Europe. This fatal disease had its origin in

Egypt. In 1399 the plague broke out in Italy for the sixteenth time. In 1485 Lazarettos were established in Europe, in which strangers were confined for forty days, hence the term quarantine.

Beneficial Progress.

Since that time there has been gradual progression to ameliorate the human race from disease. But at present water supply is as little thought of as was formerly ventilation. It is well-known that vaccination will wholly remove the danger of small-pox, but people neglect this precaution from prejudice. California has taken a decided step in the right direction by the formation of a State Board of Health to advise upon general sanitary rules that shall be uniformly applied to all towns of the State. In conclusion, the lecturer urged that we use energy, trace out the true laws of health and apply the practical knowledge of the Athenians, if we would have strong and vigorous constitutions and enjoy a healthful, long life.

Good Food and Good Health.

Upon this topic Professor Blot thus expresses himself: "The man who does not use his brain to select and prepare his food is not above the hordes that take it in the raw state. It is to the physique what education is to the mind, coarse or refined. Good and well prepared food beautifies the physique the same as a good and well directed education beautifies the mind. People's taste is in food as in dress, differing not only in colors, but also in shape, therefore by our variety of dishes and our different styles of decorating them, by the ease that they can be prepared in the cheapest as well as in the most costly way, we think we meet all wants and tastes. In fact, to use a very trite remark, 'you cannot make a gentleman by feeding him on codfish.' There is no country where there is so much dyspepsia as in America, because our people pay but little attention to food and eat too much meat for the exercise they take. If one has mental labor, fish every second day, at least is requisite. Soup sets all the glands at work, and prepares the stomach for the most important function of digestion, and therefore should be taken at dinner every day. Beef broth is to old age what milk is to the young. Cookery properly attended to keeps man in health, if the stomach is out of order the brain is affected. We have the soft and hard parts in our anatomy, and the bile, and therefore it is requisite to vary our food. We should eat more fruits, vegetables, soup and fish. Fish and cheese are the best articles of diet to give to children. United States has the most money of any people, and the greatest abundance of raw material, yet they live more poorly comparatively than any civilized nation. For instance there is a millionaire in Brooklyn who has pork and beans every second day for dinner. Wrinkles are produced by the want of a variety of food."

LIGHT CLOTHING.—In clothing the human body this principle should be kept constantly in view, viz: Let the clothing be as light as possible consistent with comfort. Every pound of clothing beyond this constitutes a useless and constant burden. Besides this, it presses upon and interferes with the action of the skin. Adherence to this principle also implies an equal distribution of clothing over the entire body.

DANGEROUS HOLLOW WARE ENAMEL.—A Prussian physician has examined the enamel on hollow-ware sold in Berlin, and reports that the enamel on a stew-pan made in Belgium contained so much lead that $2\frac{1}{4}$ grains of oxide of lead was found dissolved in one litre of vinegar (3 per cent acetic acid) which had been hoiled in it for one hour.

Hall's Journal of Health says: "The old and young delight in warmth; it is to them the greatest luxury. Half the diseases of humanity would be swept from existence if the human body were kept comfortably warm all the time."

A GOOD LINIMENT.—One of the very best liniments that was ever made for man or beast, is composed of equal parts of laudanum, alcohol and oil of worm wood.

KILLING KNOTS.—Glue size and red lead gum shellac dissolved in alcohol, and mixed with red lead gutta percha dissolved in ether. But through all or any of these will the pitch of the knot exude if exposed to the sun? Perhaps the very best method is, to size the knot with oil size, and then lay a leaf of gold or silver on it. In a very choice piece of work, a hot iron may be held over the knot till a good portion of the pitch has come out and been scraped off, when the two coats of the leaf will be sure to keep out both the pitch and any discoloration.

THE MOON'S ATMOSPHERE.—If the atmosphere of the moon really exists, its density is less than the 2,000th part of the density of the earth's atmosphere. Such an atmosphere would be more attenuated than the vacuum which is obtained, under the best conditions, in the most perfect air-pumps. The refraction, or rather non-refraction of stars, is the means by which this determination is obtained.

MISCELLANEOUS.

Onions.

Onions can be used in many ways, though they do not range high in nutritious qualities. The odoriferous are altogether too high until well cooked. Like cabbage, they are almost indispensable to meat and vegetable soups. They are good also for stews. A delicious little stew, into which I was led by the favor shown to "Mallium," can be made of about equal parts onion, potato, and apple. Peel and quarter three onions, and put them to stew in double their measure of water for forty-five minutes, (for red or yellow onions one hour). Then cut up and add three medium-sized potatoes, and three apples, pared, quartered, and cored. Then, upon one gill of wheat meal, pour boiling water enough to scald it, stirring it lightly; and when the stew boils up, after putting in the potatoes and apples, add this dough, in bits as big as an almond, and not compact. Cover close and dish the stew; and if the liquid is too thin, add a little wheat meal: salt and pour over the stew and serve warm. Rutabagas and parsnips can be used instead of the apples, but they require more time to cook, and are not so delicate. If meat is wanted in these stews, use the lean of mutton, not lamb nor veal.

Perhaps a word of caution is necessary at this time of the year about young meat. It contains very little nutrition (probably because, not fully formed), and that little does not seem to be well adapted to our wants. In many cases, the effects of eating it have seemed little short of poisonous. It is the best economy to kill the calves at once, if there are any to be disposed of, or keep them until they are at least a year old.—*Science of Health*

RYE FLOUR BREAD.—Take as much flour as you wish for one baking of bread; make a hole in the centre of the flour and stir into it one teaspoon of good hop yeast and one pint of new milk. Stir the batter a little stiffer than for griddle cakes. Then cover closely and let it rise over night. In the morning add more new milk, and knead up your bread very stiff. Then with your fist make a hole through the centre of the dough, and let it raise until it is even on the top. Your bread is then ready to put in the pans for the third raising, which will take about half an hour. Bake as you would wheat bread. Salt it if you like. I have made most excellent bread in this way. It is also good to mix two-thirds wheat flour to one of rye.—*W. Rural.*

CALF'S HEAD PIE.—Boil a small calf's head or half a large one, take all the meat from the bones, blanch and keep the brains separately, skin the palate, tongue, etc., and cut the latter into thin slices. Season with spices according to taste. Shape the meat for a few moments in a hot pan over a brisk fire. Put a rim or crust around your dish, lay in the meat, filling up with the yolk of eggs hard-boiled, pieces of the brains, forcemeat balls, and a little minced anchovy. Finish with a cupful of good gravy, and cover with a crust. A few flat sausages may take the place of the forcemeat balls, but they must be very highly seasoned, or the pie will be insipid. Oysters are likewise admissible.—*Ohio Journal.*

PICKLED LEMONS.—Take small lemons with thick rinds, and rub them with a piece of flannel; then slice them half down in four quarters, but not through to the pulp; fill the slit with salt pressed hard in; set them upright in a pan for four or five days, until the salt melts; turn them thrice a day in their own liquor until tender. Make enough pickle to cover them of good vinegar, the brine of the lemons, Jamaica pepper and ginger; boil and skim it; and when cold put it to the lemons with two ounces of mustard seed, and two cloves or garlic to every six lemons. When the lemons are used, the pickle will be useful in fish and other sauces.

CORN-MEAL BREAD.—Pour over a pint of nice corn meal one pint of hot new milk; beat this well and add a little salt; then stir in a large spoonful of nice, sweet lard; beat two eggs very light and stir in also; this must be well beaten, and of the consistency of thin batter; add more milk if it should be too thick; then mix in a large spoonful of yeast; batter the pans and set it to rise in them; when risen, have the oven of a moderate heat, and put them in it; bake two hours and a half to a light brown. Serve hot.

HOW TO PREPARE TURNIPS FOR DINNER.—Take of good turnips and potatoes enough to make two quarts of each, after being peeled and cut. Two or three pounds of fresh beef or pork, of medium fatness, should be hoiled for an hour, to which the turnips and potatoes are to be added; boil the whole half an hour longer, then add half a teaspoon of both sugar and flour, and hoil five minutes longer. When done, they ought to be mashed the same as usual.

CREAMEN POTATOES.—Have ready some potatoes hoiled or steamed, and cut into slices; place them in a stewpan with a coffee-cupful of good thick cream, a desert spoonful of flour, some salt and crushed pepper, grated nutmeg, chopped parsley, and minced onions. Mix thoroughly, put upon the fire until scalding hot, but not hoiling, and serve quickly.

San Francisco:

Saturday Morning, March 29, 1873.

Legal Tender Rates.—S. F., Thurs., Mar. 27.—buying 87½; selling 87½.

Table of Contents.

GENERAL EDITORIALS.—The Spectroscope.—An interesting Lecture: The Age of Steel; 198. Danger from Falling Meteors; America at the Vienna Exposition; San Francisco Directory for 1873, 200. Foundry Work.—The Ridsdon Iron and Locomotive Works, 201. **ILLUSTRATIONS.**—Around the Camp Fire, 193. The Supple Needle; An Easy-Riding Sully, 201.

CORRESPONDENCE.—New York Capital in Mining, 194.

SCIENTIFIC PROGRESS.—Is Intellectual Labor a Transformation of Heat; Cause of Rust in Iron; Electricity; Crystallization; Process for Extracting Gold and Silver from Copper Pyrites; Refining Gold by Chlorine Gas; Natural Sulphuric Acid; Improvement in the Manufacture of Sulphuric Acid; Measuring Thousandths of Inches; A New Experiment, 195.

MECHANICAL PROGRESS.—Effects of Magnetism Upon Iron and Steel; Steel Rails; Railway Brakes; To Determine the Dimensions of Fly Wheels; Slate Roofing; An Improved Cask, 195.

USEFUL INFORMATION.—Value of Sweepings; Green Varnish; To Preserve Books; Popular Fallacies; Variety in Colors; Elasticity of Springs; Cold as a Food Preserver; A Substitute for Ivory; A Hundred Years Ago; Singular Chemical Transformation; Stopping Runaway Horses; Novel Mode of Measuring the Height of Trees; Chinese Labor; A Fortune from Lamp Chimneys, 199.

GOOD HEALTH.—Sanitary Conditions; Good Food and Good Health; Light Clothing; Dangerous Hollow Ware Examined, 199.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 196.

MINING SUMMARY from various counties in California, Nevada, Arizona and Utah, 197.

MISCELLANEOUS.—Hale and Norcross Mine; Deep Placer Mining; Map of Little Cottonwood; Agassiz Museum; Cinnabar; Manufactures of the United States; Capital in Utah, 194. The Sutor Tunnel of Pioche District—The Pacific; Utah Mining Matters, 198. Killing Knots; The Moon's Atmosphere; Onions; Rye Flour Bread; Cal's Head Pie; Pickled Lemons; Corn-Meal Bread; How to Prepare Turnips for Dinner; Creamed Potatoes, 193. Highland District and the Mendocino Mill; How to Search for Metals; The Material Prosperity of Utah; Soot Sheds; Mining in England; Important Mining Decisions; Mining Expedition; Ore Shipments, 202. The Emma Mine, 204.

SPANISH PROGRESS.—The new Republic of Spain has taken a wise step and abolished slavery in the Island of Porto Rico. The number of slaves set free is about 50,000. It is to be hoped that the Spanish Cortes will now take into consideration the abolition of slavery in Cuba, and emancipate its 360,000 slaves. The latter subject has been under discussion.

UP THE NILE BY STEAM.—This is the title of a little volume of 75 pages by R. Etzenberger, full of valuable and interesting information to persons making the tour of Egypt, and particularly the trip from lower to upper Egypt by steamer on the Nile. No traveler to that land of wonders and ancient civilization should be without it. For sale by Thomas Cook & Son, London.

A PECULIAR FISH.—A remarkable fish from Humboldt Bay is now on exhibition in this city. It is 3½ feet long with a slender eel-like body and a large head with a mouth like a crocodile's. The teeth are sharp and transparent, sloping backward from the jaws. Immediately back of the head commences a large winglike fin, about six inches high when erect, which runs the length of the back. The fish was found dead on the beach, and is preserved in alcohol.

AGASSIZ'S MUSEUM.—The Committee of Education in the Senate has reported a resolution appropriating \$50,000 for Professor Agassiz's Museum at Cambridge, Mass.

BORATE DEPOSIT.—An extensive borate deposit has been discovered about 120 miles from Los Angeles on the Owens River Road, in Kern county. Other deposits are reported 60 miles distant from Los Angeles in the State range, North of Desert Springs. The place are being thoroughly prospected.

Danger from Falling Meteors.

Information has been conveyed to the British Royal Society, and published in the last number of their "Proceedings" to the effect that during the appearance of the meteoric display on the night of the 13th of November last, the night watch upon a light ship, stationed off the north coast of the Sicily Islands, was struck senseless by a meteor, and that the decks of the ship were covered with fine cinders, supposed to have been derived from the falling dust of consumed meteors. The watchman appears to have been struck down at the very commencement of the meteoric shower, but after his return to consciousness he saw "balls of fire like large stars, falling into the water like splendid fire-works," and accompanied with a strong smell of brimstone. The brimstone smell was no doubt due to the abundant production of ozone in the atmosphere by the rapidly moving and glowing bodies of the meteorites.

It is fortunate for mankind that meteoric bodies for the most part are so small that they are almost instantly dissipated on coming into our atmosphere, by the great friction and intense heat generated by their rapid motion through the same. The motion of a meteor through space, is many times more rapid than that of a cannon ball, during the first second of its discharge. Indeed, even a twenty or fifty pound ball, if projected with a force which would give it the speed of a meteor, would be dissipated before it could reach the distance due to its initial discharge.

Oxidizable bodies, under such circumstances (and all meteors as well as cannon balls are extremely oxidizable) are not converted into gases, but undergo a rapid oxidation or burning-up process, by reason of the large amount of oxygen with which they come in contact during their rapid flight; disappearing just as a piece of steel "burns up" when heated and tipped with a little brimstone, and plunged into an atmosphere of pure oxygen; as is often seen in lecture experiments. Perhaps a better illustration is the frequent practice at the camp-fire, when it burns low, of picking up two or three almost expiring brands, holding them close together and whirling them rapidly around until they burst into a flame, and therewith renewing the camp-fire.

Were it possible for any considerable portion of the great number of meteors which flame through the sky, especially at the time of their periodical display, to reach the earth, in their flight, much danger might be apprehended to life and limb.

A bombardment of cannon balls from an aerial fort (with their comparatively slow motion) and equal in frequency to the appearance of meteors in our August and November showers, and sweeping as those displays do, completely around the earth—the earth rather plunging directly into the midst of the meteoric orbit—would be a calamity dreadful to contemplate, and the frequent occurrence of which might almost depopulate our planet.

It is only now and then, however, that we encounter meteors of dangerous dimensions. In fact, their infrequency is considered a matter of serious inconvenience to scientists, who would like to meet with them much oftener, to the end that they may the more readily fill up their cabinets with specimens of these aerial wanderers.

LOCOMOTIVES.—California has a great many narrow-gauge railroads projected and a few in course of construction, for which rolling stock will of course be needed. The style of locomotives to be used is an important consideration, as the successful operation of a few roads in this State will eventually cause others to be built. The National Locomotive Works of Dawson and Bailey, at Connelville, Pa., whose card will be found in another column, are manufacturing a very superior class of locomotives, and give special attention to those intended for narrow-gauge roads. They have built a number of engines for roads in the Southern States, Utah, Nevada and South America, and for coal roads in Ohio, Pennsylvania and other States, all of which are said to be giving satisfaction. Their mining locomotives are extensively used in the coal mines of Western Pennsylvania. Parties interested in narrow gauge railroads and mining operations, who desire to do so, can examine drawings and ascertain particulars at the office of Capt. H. A. Gorley, No. 521 Front street, that gentleman being agent for the above firm.

America at the Vienna Exposition.

It is gratifying to learn that notwithstanding the small amount of the appropriation by Congress, and the drawbacks occasioned by the patent laws of Austria, that American manufacturers will be creditably represented at the Vienna Exposition. It is now stated that there will be upwards of 550 more exhibitors than there were at the Paris Exposition of 1867. The display of American Agricultural implements—a very important one—will of itself occupy a space of about 15,000 square feet, and will comprise the work of 25 different manufactures. The machine in motion will occupy a space of 15,000 feet and will be contributed by 150 firms. The specimens, which include almost every machine capable of being propelled by steam power, will be run by four American engines. In this particular an improvement is made upon the Paris Exposition, where our machinery was run by foreign steam power. The department of "machinery not in motion" will represent 150 manufacturers, and occupy a space of 15,000 feet. The Northern Pacific Railroad Co. have contributed a large number of specimens of agricultural, mineral and other productions of the "New Northwest." A collection of maps, volumes of statistics, photographs, etc., has been sent by the American Geographical Society. There will be a collection of over 7,000 American daily, weekly and monthly periodicals.

The department of minerals, ores, etc., is reported to be very full and includes minerals and ores from all the principal States of the Union, including silver and gold quartz from this State, and specimens of coal from all the leading mines of the nation, accompanied by comprehensive maps showing the territory covered by the respective specimens. Unfortunately the lack of interest shown in this Exposition here in California, and in fact on all of the Pacific Coast, has prevented an appropriate collection being made. As exhibitors had to pay the expenses of transportation from here to New York they were unwilling to take the trouble and risk of sending anything very valuable. We are certain that the mineral products of this Coast, the most important and varied in the United States, will be slimly represented, but the coal and iron interests of the Eastern States will nevertheless make a good show. Several gentlemen who went to Vienna from this Coast endeavored personally to collect specimens enough to represent us fairly but hardly succeeded. They had not the time to spare to visit the many different mines, and as few people took the trouble to send specimens the collection will be comparatively meagre. Messrs. Booth & Co., of the Union Iron Works, in this city, intended to have forwarded a complete 10-stamp California mill, with all the usual appliances, which would probably have been the best characteristic California representation at the Exhibition. Mr. Guido Kustel, well known to our mining community, was to superintend its operation at Vienna. A special exhibition was intended, and a sum of money was to be raised to defray expenses. The mill was to be the share contributed by Messrs. Booth & Co. Unfortunately the others failed to raise the necessary funds, and the project fell through, so the mill did not go. Professor Blake has been appointed Commissioner to the Exhibition and we will no doubt have some very interesting and exhaustive reports in relation to the mining industry which is represented.

The sugar and cotton interests of the South will be well represented, and rice, ramie, tobacco, etc., etc., will be shown in all the various stages of its growth and manufacture. Among the features likely to attract general notice will be machines for the manufacture in the presence of visitors of palls and shoes, spinning, knitting, sewing-cloth, cutting and even a writing machine. There will be a full representation of printing presses and two daily papers will be printed under the auspices of the American Commissioners. Musical instruments will be shown in profusion. American Art will be, however, but slimly represented. A model school-house, with furniture and text-books complete, has been sent. The exhibitors who sent articles to this Fair number 300 in all. After all that has been said against Americans showing their goods at Vienna, it is satisfactory to know that such a respectable representation will be made. An International Patent Rights Congress, composed of manufacturers, scientific men and experts, will be held at Vienna during the Exhibition.

THE OHIO STRIKE.—A dispatch from Youngtown, O., dated the 24th, says that on the arrival of an armed force from town, Friday night, at the Mahoning Coal Company's mines, the rioters who were there in large force, and had commenced hostile demonstrations, dispersed, and the immigrants employed to take their places, went into the mines unmolested. On Saturday morning, the strikers again attempted to intimidate them, but were unsuccessful, the guards preventing a collision. The breach between the strikers and coal operators is growing wider, and to put an end to the strike, the operators intend to import 1,000 or 2,000 immigrants. This is a new way of getting out of the difficulty surely.

San Francisco Directory for 1873.

Langley's San Francisco Directory for 1873 was issued some ten days since, and presents a formidable volume of 884 pages, besides some 200 pages of advertisements. The regular annual increase in the volume of this valuable compilation, affords an excellent index of the rapid growth of San Francisco. Every succeeding volume also brings fresh and interesting facts for the study and consideration of our people. The compiler, in the present issue, opens his prefatory remarks with the following encouraging statement:

At no previous period of the city's history could there have been presented a more favorable record of a twelve-months' progress than the one contained in the present volume. In almost every department will be found abundant indications of a growing and healthy improvement, and when the facts and figures contained therein are carefully considered, no better evidences need be required to substantiate the present prosperous condition of this city, or to predict for its future, a prominent position among the leading commercial cities of the world.

The General Register contains 69,403 names. The number of references contained in the present volume is 100,903. The population of the city is estimated at 188,323, a gain since March, 1872, of 10,047, or over five and one half per cent. The number of buildings erected during the year ending February 28, 1873, is about 600, at an estimated cost of \$3,750,000. Total number of buildings in the city is 20,887.

The increase of population, for the year has not, for various well known reasons, been quite up to the previous ratio; yet basing the increase for the next ten years upon the ratio of the year just passed, San Francisco will have a population in 1883 of very nearly 300,000! We can hardly suppose that the suburban drain can bear any greater proportion to our population, at any time during the next ten years, than it has done for the year past, nor that railroad uncertainties or any other ordinary drawback to our natural increase can be in excess of what we have experienced during the past twelve months. Hence we infer that the figures above assumed will be fully realized in 1883.

The volume before us, which is the 14th of the series, contains a vast amount of valuable and interesting statistical information connected with the municipal organization, our public schools, banking institutions, insurance companies, religious and charitable institutions, general industries, etc. The book has evidently been prepared with great care; the arrangement of the matter is well made and all the details evince skill, care and patient industry. The Directory is a credit not only to its compiler, but to the city itself. It is from the press of Valentine & Co.

A New Canteen.

Richard Kelly, of Red Bank, Tehama Co., in this State, has recently procured through the SCIENTIFIC PRESS Patent Agency, letters patent for an improved Canteen or water-carrier. Mr. Kelly proposes to make the canteen out of canvas or other thick and almost waterproof cloth, which will keep constantly saturated with the contained water, so that the evaporation from the outside of the canteen will keep the water inside cool and refreshing as long as any remains in the canteen. He also attaches to the canteen a filtering sack through which the water is passed in filling the canteen, thus enabling the traveler to use water which would be otherwise unfit for drinking purposes. This invention will be appreciated by all who know the value of a pure and cool drink of water in the hot and sultry days of summer, especially in those neighborhoods where water is scarce, and what little there is is unfit to drink. Mr. Kelly proposes to immediately manufacture a quantity of his canteens for general use, so that farmers can apply themselves with them for use in the coming harvest.

THE DIAMOND SWINDLE.—The telegraph announces that on Monday the civil suit of William M. Lent against Phillip Arnold and Robert Slack, for \$350,000, was dismissed in the United States District Court at Louisville, Kentucky, by consent of the parties. Arnold having compromised with Lent by paying him \$150,000 in greenbacks and each party to pay their own costs.

THE SHIPMENTS OF COOS BAY COAL TO SAN FRANCISCO during January and February this year, amounted to 6,059 tons. This will be largely increased in March and April.

Suplee Needles—Their Manufacture in San Francisco.

The Suplee needle is a recent California invention and one which is destined to do away entirely with the old-fashioned sewing machine needles so long in use. It differs from all other sewing machine needles by having an open eye or slit so arranged that it can be threaded instantly by taking the thread in both hands as shown in the accompanying cut, placing it at the eye, and pulling it gently against the needle with a downward motion. This dispenses at once with the slow process of biting off the thread and twisting the end into a point so as to get it through the ordinary eye. The saving of time alone is an item in its favor, without taking into consideration the trouble incident to threading old-fashioned needles. The manufacture of sewing machine needles in the United States has heretofore been confined almost exclusively to North Bridgewater, Mass., but a factory for turning out needles of this patent is now under way in this city, owned by the Suplee Needle Company.

We recently paid a visit to this factory, which is located at the corner of Sansome and Sacramento streets, and found the process of manufacture very interesting. The tools used are delicately constructed and highly finished, the majority of them having been made in this city. The needles are made from the best English steel wire. The wire is first straightened and a machine then cuts it to the proper size, by means of a minute circular saw, and performs the blank shaping of the wire for the stamping machine which makes the shank. The shank is made in the same manner that paper is stamped. The shank is then grooved by an instrument which has two small circular saws close together, between which the shank is placed and the two grooves, one on each side, but one larger than the other, are cut at the same time. One operator can work two of these machines, a great improvement over the old way when only one groove could be cut at a time. The neatest little machine in the shop is the drill which is a marvel of nicety, running at about 2,500 revolutions per minute. This drills the eye of the needle, this part of the process differing from that in vogue in Europe where the eyes are punched. The foreman, Mr. A. B. Holmes, informed us, however, that the drill makes a much smoother eye than the punch, performing the work more thoroughly. The eye, which is after drilling only round, has to be reamed out to be made oblong. This is done by a small tool placed in a turning lathe. To produce the slit in the eye which is the important feature in the Suplee needle, the half-formed needle is then placed in a clamp and the slits cut with a fine circular saw. It is then cleaned by revolving metallic and ordinary brushes. The needles are curved to conform to the style of the machine upon which they are to be used, as different curvatures are necessary on machines of different patents. This operation is performed on a machine which has the *fac simile* curvature of the needle of the machine for which it is intended. The needle is then tempered, which operation is performed in another room. A number of needles are heated to the proper temperature in a small furnace and then placed in cold whale oil after which they are placed in a pot and again heated to a certain degree.

After being tempered, the needles are curved, as above stated, and then ground on a common emery wheel. After this they are wiped, polished, the eyes cleaned out, and are placed in the proper boxes, according to size, ready for sale. The workmen employed are all trained hands, educated to do this peculiar work. Some fifteen hands are now employed. The introduction of this needle to popular use has been successful, and the capacity of the factory is shortly to be increased. It adds another to our list of home manufactures, and it is to be hoped that the company will be under the necessity of obtaining more commodious quarters than they now have, to carry on their business to a greater extent. The cut accompanying this article represents an enlarged view of the Suplee needle, and shows the peculiarity of the eye. The company have also patented a neat and convenient little needle case, capable of holding 12 needles of the size adapted to the thread to be used with them. The needles are placed in different compartments, appropriately numbered to correspond with the numbers stamped on the needles; the numbers designating the thread to be used with the needles are stamped under the proper compartment.

The needle was invented by a lady, Mrs. Hannah G. Suplee, from whom it takes its name.

It is safe to predict that persons who once try the easy-threading needle, will be unwilling to use the old-style once again, as the new invention saves time, eyesight and annoyance—considerations of so much importance to persons interested, that the open-eyed needle will supersede the others. Although the open-eyed needles are not a new invention, as many attempts have been made to provide a needle for sewing machines having for their object the easy introduction of the thread to the needle, this patent succeeds in a more satisfactory manner than previous inventions. A gold medal was awarded to the inventress at the Seventh Industrial Exhibition of the Mechanics' Institute of this City. The office of the company is No. 27 New Montgomery street, where the needles may be seen in practical use.

An Improved Sulky.

People who are accustomed to ride in sulkies either for racing or training purposes are well aware of the uncomfortable jerking motion

THREADING THE SUPLEE NEEDLE. ENLARGED SUPLEE NEEDLE.

incident to them, caused by the weight of the driver being thrown principally upon the shafts, which communicate the motion of the horse. Mr. John A. Bilz, of Pleasanton, Alameda county, Cal., has recently patented, through the agency connected with this office,

the light of counterfeits, it is interesting to mark the nearness with which some imitations approach the perfection of their originals. It is hard to think that in time all the precious stones, so beautiful in themselves, will be driven from the field by imitations. This is,

AN EASY-RIDING SULKY.

an improvement, the object of which is to attach the seat to the axle in such a manner as to avoid the forward-and-back or "bobbing" movement of the rider, which is caused by the ordinary seat attachment, and thus render riding in this class of vehicle much more pleasant.

The accompanying cut is a representation of this device. *B* represents the axle of any sulky or two-wheeled vehicle. The shafts are attached to the axle in the ordinary method. *D D* are two curved springs, one end of which is secured to the axle, while the opposite ends support the rear of the seat, being rigidly secured to it. These springs can be made of metal or wood, the latter being, however, preferable. The front of the seat is supported by metal springs, *E*, which are also bent in the form of a *C*. The lower ends of these springs are attached to a plate, *F*, by a joint, and the plate, *F*, is fixed to the cross bar of the shafts. The upper ends pass through a projecting lug, *H*, which descends from the bottom of the seat, and is attached forward of this lug by a hinged joint at *i*, to the front of the seat. A block of hard rubber or other

elastic substance, *K*, is fitted between the end of the spring, *E*, and the bottom of the seat, which gives a long elastic bearing for the spring by which it is relieved from sudden shocks or strains.

By this arrangement the weight of the driver is thrown principally upon the axle, and the elastic block in connection with the springs makes the seat a comfortable one and the sulky an easy riding one.

FIRE OPALS.—A friend left at our office, the other day, some specimens of imitations of fire opals which bid fair to equal the real thing. The amount of fire and general resemblance are such as to deceive practiced judges. Though we cannot but look upon such manufactures in

PATENTS & INVENTIONS.

Telegraphic List of U. S. Patents Issued to Pacific Coast Inventors.

(REPORTED OFFICIALLY FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch, Dated Washington, D. C., March 25th, 1873.

FOR WEEK ENDING MARCH 11th, 1873.
PROCESS FOR MAKING COKE FROM LIGNITES.—Harry Eugleman, Salt Lake City, Utah.
SAW HOLDER.—Henry Thomas, S. F., Cal.
ACCOUCHMENT COUCH.—Eliza Lavinia Moore, S. F., Cal.
SWIVEL HOISTING APPARATUS.—Thomas M. Martin, assignor to self and A. S. Hallidie, S. F., Cal.
WHEEL FLOW.—Louis Sachse, Monmouth, Oregon.
AGEING WINES AND LIQUORS.—Adolph Laquet, Monmouth, Oregon.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

Foundry Work—The Risdon Iron and Locomotive Works

The Risdon Works are at present running up to their full capacity, and have on hand some very large machinery. They are employing 275 men at present, and will add fifty more to this number in a week or so. The large cylinder for the steamship Arizona, of which we have before spoken, is just finished, and will be shipped to Benicia in a few days, where it will be put on board under the Bishop derrick. The condenser is already there. The cylinder bottom and valve chests are now being fitted on the cylinder, and will go to Benicia with it. The whole of the above-mentioned work—condenser, cylinder-bottom, valve-chest and piston were cast perfect the first time—something remarkable, when it is considered that either piece is called a heavy casting—the five pieces amounting to over 100,000 lbs. weight.

The large machinery made for the Imperial mine has all been shipped, except the pump gears, just being finished, and weighing 22 tons. This part was detained on account of the great weight breaking down one of the tools in the machine shop. This has, however, been replaced by heavier machinery, capable of making even larger gears than these. The engine for the revenue cutter is nearly ready for the boat, which is expected to be launched at the next spring tides; the boiler and shaft are already in place. The propeller is made of brass, weighs 4,200 pounds, and was cast at this establishment.

A visit to the shipyard at the Portrero would pay those interested in ship-building, about which so much is being said at present. It reflects great credit upon the builders (Dickey Bros.), and if good work will secure to California the building of her own Revenue Cutters, Captain White, under whose supervision this one is being built, is determined we shall deserve it.

The boiler department of the Risdon Works is engaged in making the water pipe for the Virginia Water Works, 36,500 feet long, 12 inches in diameter. They are building a complete set of hydraulic machinery to work the pipe, having a steam pump, accumulator, hoist, etc., working under a pressure of two thousand pounds to the square inch. A number of other jobs are in course of construction more or less advanced. The orders for our wheels keep the foundry busy and it is supplying the various railroads, street railroads and mines with regular chilled iron.

MORE COAL.—Other deposits of coal have been found in Contra Costa county, at different points on the proposed line of the narrow-gauge road from Oakland to Contra Costa county. It has the appearance of being better than any yet found upon this coast. It bears a general likeness to the English cannel coal.

TRADE SCHOOLS.—The idea of teaching trades in connection with schools has been practically adopted at a school in Vienna where girls are taught type-setting.

THE PENNSYLVANIA Central Railroad Company owns and controls 5,000 miles of railroad valued at \$300,000,000.

THE CIRCULATION of the two gold note banks in this city, was on the 18th inst. \$1,124,340 in gold notes.

we believe, the first successful attempt to imitate the fire opal. The maker will no doubt have a good thing of it.

MR. LOUIS JANIN, the well-known mining expert, will shortly leave for Japan on professional business. He goes, we understand, in the employ of English gentlemen under engagement for one year at a salary of \$1,000 per month, with his expenses paid. He has purchased an extensive assaying and engraving apparatus to take with him.

THE Pacific Iron Company has been incorporated in Portland, for the very important work of manufacturing railroad and merchantable iron.

MR. GEORGE ATTWOOD, son of Melville Attwood, M. E., has been appointed resident manager of the famous Emma mine, in Utah.

THE HORSE DISEASE is interfering with the shipment of bullion from the Cerro Gordo mines.

Highland District and the Mendha Mill.

The editor of the *Pioche Record* has been making a visit to Highland District and the Mendha Mill and has gathered the following notes:

Highland is, as the crow flies, about four miles west of Pioche, but the district by the wagon road, is about 7½ miles. The increasing interest which is being felt here in Highland District made us glad that the opportunity had been thus offered to ascertain its progress, prospects and resources from personal observation, and we at once decided to avail ourselves of it to the fullest extent.

The Mendha Mill.

We found Mr. J. B. White on the ground, who is erecting the new Mendha 20-stamp mill under contract—being the gentleman who erected the Magnet and American Flag mills, and the Raymond and Ely mills. Mr. White politely showed us every attention in taking notes of the construction of the Mendha mill. All the material was on the ground, and much of it in place. It will probably be the strongest and most substantial mill in the State, as the Superintendent has refused to accept machinery and material of all kinds which was not first-class, and all the late improvements have been secured. The foundation timbers of the mortar-beds are two feet square, full measure, and 14 feet long. They were sawed out 40 miles northeast of Pioche. We had thought such large timbers could not be procured within that distance. The main battery posts were procured in the same locality, and are nearly as large. Some of them are 12x24 inches, and the others 20x24 inches, clean sawed, and they are all 24 feet long. The main boxes of the battery are 20x12 inches square and 26 feet long.

Engine and Boiler Room.

The engine and boiler room will be 36x38 feet, and 16 feet between joists. The north side wall is constructed of gray limestone, three feet thick and 14 feet high, with a wall-angle between the boiler and battery rooms of the same character, the masonry being of the strongest and most particular kind, strength and durability being controlling considerations in its execution.

Battery Room.

The battery-room is 40x42 feet in the clear. The battery pit is 26 feet long, 5½ feet wide, and 9 feet deep. It will be filled in with carefully screened sand, which will be tamped in every part with hot irons, thus insuring greater firmness and solidity than could be attained by any style of rock-and-mortar masonry—in fact, a solid porphyry block could not be stronger. Over this 20 stamps will be put in operation, of 750 pounds each.

The Steam-Works.

We will be better able to give a detailed description of the steam-works of the Mendha mill after they get into operation. The engine cylinder is 16 inches in diameter, and has a thirty-inch stroke. The power is 35-horse. The boilers are 43 inches in diameter in the clear, and 16 feet long, with large steam and mud drums attached. Connected are all the latest improvements in the application of steam power to quartz mills. Every part of the machinery was made expressly to fill the order of the Mendha company, and a more complete and perfect bill was never shipped from San Francisco. The machinery was all manufactured in the Union Iron Works, of that city.

Strength of Construction.

The mill is durably and powerfully braced throughout—on all sides and at all points. The pan and settler frames are undoubtedly the strongest in the State, the timbers used for the purpose being the largest that could be procured in the forests of southeastern Nevada. The breast-wall back of the pane is three feet thick and eight feet high. Extending up through the center of the wall are wrought anchor-bolts of one and a quarter inch iron. On the east side are belt-pit walls three feet thick, being four feet apart. Massive wrought iron bolts extend up through the inside wall to hold firmly the machinery above. A solid wall of gray limestone and porphyry extends along the entire north side of the building. The mortar was made of an excellent fire-clay, which is found in abundance three-quarters of a mile from the mill-site, and the best sand for the purpose, composed of disintegrated porphyry with the felspar washed out was found right at hand. The mason work was all done under the supervision of Mr. Terry Maginnis, a mason of great experience and rare skill.

The Roasting Furnace.

To the west of main building is being erected a Stetefeldt furnace for roasting the ores. The interior of the furnace establishment will be 36x30 feet. The furnace will be twenty feet and five inches long, eight feet and two inches wide,—exterior measurement, of course—and twenty-eight feet high. The dust-chamber attachment is of the most approved pattern. The drying surface is immense, embracing 414 square feet. The foundations are of fire-proof porphyry, which was quarried out a half a mile from the mill-site, with thick walls of porphyry and brick.

The Blacksmith Department.

Under the supervision of J. J. Paul, is very complete. Among its facilities are patent punching machines, full sets of screw-plates, the best of forges, etc.

The General Supervision.

Without wishing to detract from the credit due Mr. White, the contractor, for the energetic, skillful and efficient manner in which he has directed the mechanical work of constructing the Mendha mill, in all departments, we must commend the judgment and tireless vigilance of Professor Mathey in carrying his general supervision to the most minute details. Confident of the financial success of the enterprise—knowing, from his own personal tests and observations, that rich ores are owned by the Mendha company in inexhaustible deposits—he has all improvements made with a view to permanency, and there is scarcely a bolt or stick of timber in the Mendha mill, or to be put into it, which has not passed or will not pass his personal inspection. Though a scientific gentleman, having been educated in the mining department of one of the first institutions of learning in Paris, he has had years of experience in mining and milling gold and silver ores, and is eminently practical in all he undertakes.

Location and Water Supply.

The Mendha mill is situated in a beautiful little glen, which is walled in on the south and west by picturesque, cedar-covered mountains. At the head of a cañon to the southeast, a little over a mile distant, are prolific and ever-flowing springs, which Professor Mathey has secured in the name of the company. By a system of pipe conductors this water is all brought down to a large reservoir at the west of the mill. There is at hand a large supply of hose in case of an outbreak of fire.

How to Search for Metals.

Searching for Gold.

The paying localities of gold deposits are the slopes of mountains. Gold need not be looked for in the anthracite and bituminous coal fields, nor in limestone rock. The thing itself is the surest indication of its existence. If soil or sand is washed, and the particles of gold are not heavy enough to remain at the bottom, but float away, the bed will not pay.

Along streams rather high up among the mountains, and in the gravelly drift covering the lower slopes, are the best prospects. Where the stream meets an obstacle in its path, or makes a bend, or has deepholes, there we may look for "pockets" of gold. Black or red sands are usually richest. Gold bearing rock is a slate or granite abounding in rusty looking quartz veins, the latter containing iron pyrites or cavities. Almost all iron pyrites and silver ores may be worked for gold. When the quartz veins are thin and numerous rather than massive, and lie near the surface, they are considered most profitable. As traces of gold may be found almost everywhere, no one should indulge in speculation before calculating the percentage and the cost of extraction.

Gold hunting is a lottery with more blanks than prizes.

The substances most frequently mistaken for gold are iron pyrites, copper pyrites and mica. The precious metal is easily distinguished from these by its malleability (flattening under the hammer) and its great weight, sinking rapidly in water.

Searching for Silver.

This metal is usually found with lead ore and native copper. Slates and sandstones intersected by igneous rocks, as trap and porphyry, are good localities. Pure silver is often found in or near iron ores and the dark brown zincblende. The Colorado silver lodes are porous at the surface and colored more or less red or green. Any rock suspected of containing silver should be powdered and dissolved in nitric acid. Pour off the liquid and add to it a solution of salt. If a white powder falls to the bottom, which, upon exposure, turns black, there is silver in it. Silver mines increase in value as in depth, whereas gold diminishes as we descend.

Searching for Copper.

The copper ores, after exposure, or after being dipped in vinegar are almost invariably green on the surface. They are most abundant near trap dykes. The pyrites are generally found in lead mines, and in granite and clay slate. Copper very rarely occurs in new formations, as along the Gulf borders, and in the Mississippi valley south of Cairo.

Searching for Lead.

Lead is seldom discovered in the surface soil. It is also in vain to look for it in coal regions. It must be sought in limestone and slate rocks. A surface cut by frequent ravines, or covered by vegetation in lines, indicates mineral crevices. The galena from the slate is said to contain more silver than that from the limestone. The purest specimens of galena are poorest in silver; the small veins are richest in the more precious metal. A lead vein is thickest in limestone, thinner in sandstone, and thinnest in slate.

Searching for Iron.

Any heavy mineral of a black, brown, or yellow color may be suspected to be iron. To prove it, dissolve some in sulphuric acid and pour in an infusion of nut gall or oak bark; if it turns black, iron is present. If a ton of rich magnetic ore costs more than \$1 at the furnace, good hematite more than \$3, and poor ore more than \$1.50 or \$2, they are too expensive to pay, unless iron is unusually high.

Deep mining for iron is not profitable. Generally speaking, a bed of good iron ore, a foot thick, will repay the cost of stripping it of soil, etc., twelve feet thick. Red and yellow earths, called ochre, contain iron. Magnetic ore is easily found by a compass.—*Orion's Underground Treasures.*

The Material Prosperity of Utah.

A letter from Salt Lake City to the New York *Tribune* gives an interesting resume of the progress of Utah during the past year. The following are some of the statistics:

Utah produced about 5,000 tons of ore in 1870; calling one ton of bullion equal to three tons of ore; about 20,000 tons in 1871; and, reducing the bullion to ore at the same rate, about 27,000 tons in 1872. The statistics are easily got at, because, substantially, the entire production is carried by the Utah Central Railroad, either in ore or bullion. The value of ore and bullion produced in 1872 is a little more than \$3,000,000. A much larger proportion of the ore mined was reduced here in 1872 than in 1871; the bullion yield for that year being, in round numbers, 1,100 tons and for last year 5,500. There are now thirty to forty smelting furnaces in the Territory, calculated to be able to reduce 150,000 tons a year. It may be thought strange that with such an ore-reducing capacity the product of bullion should be but 5,500 tons. The reason, in brief, is because there is a great deal more smelting capacity than ore at present, and a great deal more cheap "blowing" than either. The territory has produced about three millions in value during the year, while Nevada has produced \$25,000,000; yet Utah indulges in more boasting about her mineral interests in a week than Nevada does in a year. A single mine in the latter State (the Belcher) turned out 83,000 tons of ore in 1872, worth \$57.63 per ton, of which \$37.12 per ton was cleared.

Comparisons are odious, but so much and such groundless misrepresentation, to draw it mildly, is exceedingly tiresome. Statements that there are a half dozen mines in Utah, dividing their millions in dividends every year; that the production in 1872 was \$18,000,000; that, as Mr. Bushnell writes you, it is likely to be \$100,000,000 between 1872 and 1877—four years—are flying in every direction all over the world. The Territory is prosperous, the mines are being opened and improved, furnaces and mills are going up, new mines are being discovered, and new fields plowed, railroads are building, and new ones projected wherever desirable; the truth is the truth, and is good enough; the production of silver, lead, copper and perhaps some other metals, is likely to steadily increase for a number of years; and it has room to do so for at least ten years before it will be in value what is already claimed for it. If Utah shall be producing altogether from her mineral resources \$10,000,000 annually by 1880, it will be a growth and development to be proud of.

Speaking of railroads, seventy-four miles have been completed during the past year—eighteen of the standard gauge on the Utah Southern; sixteen on the three-foot gauge, on the American Fork Railroad, and forty of the three-foot gauge of the Utah Northern, from near Coriune, on the Central Pacific to Logan, northward. There are about a dozen other roads projected, mostly narrow-gauge.

SNOW SHEDS.—The *Truckee Republican*, of March 15th, says: The railroad company have suffered much from the burning of their snow sheds in the summer and fall, and have bit upon a plan to prevent in the future any very extensive conflagration. They have already commenced putting in, between Cisco and Emigrant Gap, iron roofs and sides to the sheds. These iron fire-breaks are put up in sections of about 150 feet in length. The wooden sheds are left in sections of 1,800 feet each, the iron sections being between them. If the wooden sheds take fire, they can at the most, only burn 1,800 feet at a time, for when the fire reaches the iron sections it can go no further. The iron used for the sides and roofing is about one-sixth of an inch in thickness, and is in sections of, say seven feet long, by two and a-half feet wide. That used for roofing is corrugated or crimped, so that it has gutters to facilitate carrying off the water that may fall upon it. The crimping process also strengthens it. Without some such protection as these iron sections, the company are in danger of losing miles of shedding at a single fire. With such protection, the chances of a fire having a beginning are diminished, and only 1,800 feet can be destroyed at one time.

MINING RIOT IN ENGLAND.—A dispatch from London, dated March 20th, says: "The riot in Wolverhampton day before yesterday was between Englishmen and Irishmen employed in the coal mines in the vicinity of that town. The trouble has been brewing some days and culminated Tuesday in an open conflict. The authorities have arrested over a hundred men who participated in the riot. A dispatch from the scene of disturbance this morning says there are indications of a renewal of hostilities to day. The English miners threaten to strike unless the Irish employees are discharged. The shopkeepers of Wolverhampton, apprehending rioting and depredation, are closing their places of business and there is much alarm among the citizens."

Important Mining Decision.

A dispatch to the dailies dated Washington March 20th, has the following information: W. W. Curtis, Acting Commissioner-General of the Land Office, has rendered an important decision, granting the application of the North Bloomfield Gravel Mining Company for a patent for 1,535 acres of placer mining ground in Virgin Valley Mining District, Nevada County, Cal., situated upon unsurveyed lands. The decision recites that evidence in the case establishes the fact that the applicants have proceeded in accordance with law in all the preliminary proceedings. The claim was contested by parties interested in adverse mineral land locations, and also by Francis Blaine, claiming the lands as agricultural. The decision holds that the claims of the company do not conflict with those of Brackmeyer & Skidmore, the protestants in the case. It holds that the adverse claim filed by John Watt, to a portion of the premises, has not been made out so as to come within the contemplated operation of the sixth section of the Mining Act, for failure to comply with the requirements of the law, and it also appearing that the North Bloomfield Company became owners of the same by purchase in 1866. The adverse claim of Blaine, who alleges that a portion of the land is agricultural and is not mineral within the meaning of the Act, is rejected. The evidence shows that under the lands claimed as agricultural there is a deposit of gravel and gold, and that the company has expended nearly \$1,000,000 in developing and working these gravel mines. It appears that these premises were located for mining purposes many years ago and that said company and their grantors had sufficiently prospected and developed the same to show that said premises are mineral in character and of more value for mining than for agricultural purposes. A reference is made to the decisions of the Land Office and of the Secretary of the Interior, dated last year. In the case of Ekin Smith vs. Absalom Stewart, giving a construction to the tenth section of the Mining Act of July 26, 1866, the Register and Receiver of the Land Office at Sacramento are instructed to list the lands, accordingly, as mineral, and the claim of the mining company is granted.

MINING EXPEDITION.—A despatch from Pioche, Nev., dated the 21st inst., says: A large meeting was held last night of persons contemplating an expedition to the gold and silver fields of the Stiken river, in Northern British Columbia. A number expressed the intention of following Mr. Cargotich, the discoverer. A large party will probably go from here.

ORE SHIPMENTS.—On the 18th inst. 127 car loads of ore were shipped over the Virginia and Truckee Railroad from the Cometock mines to the Silver City and Carcon river mills. This is, we believe, the largest shipment of ore ever made.

New Inventions.

A GRATE BAR that don't burn out, for furnaces.
SHEARS for cutting grapes and flowers.
A NEW ROLLER SEATE that is superior to all others. \$6.
A DRINKING FOUNTAIN for fowls. \$1.25.
A SUPERIOR BIRD SCRAPER.
The cheapest and best FARM FENCE ever built.
A POST DRIVER that every farmer should have.
An improvement on DENTAL PLATES to hold them firmly in the mouth.
A NEW FURNACE for roasting ores.
A SASH TIGHTENER that keeps out all dust, takes the place of weights, and keeps the windows from rattling.
A new kind of BEATERS that never get out of order.
A SAND CAT that keeps all dust out of hubs.
A POTATO DIGGER that will dig a row as fast as a man can walk.
A HOUSEHOLD TOOL needed in every family. 50c.
A self-acting NUT ROASTER that works to perfection.
A NEW GAS LAMP that costs only half a cent per hour to burn.
An improvement in THILL ATTACHMENTS.
A SUPERIOR CIDER AND WINE PRESS.
The best SELF-OPENING GATE ever invented.
A FLOW on a new principle—it works to perfection in floods.
A NEW VEGETABLE CUTTER for house use.
An improved FLOW CLEVER.
A cheap and perfect POLISHING AND FLUTING IRON COMBINED. \$3. Agents wanted.
A TOY ENGINE that every boy should have for instruction.
A NEW GLASS CUTTER that beats a diamond. 50c.
A CAN OPENER that cuts any shaped hole and every size. 75c.
The best WASH BOILER ever invented.
A EGG BEATER that beats eggs in one minute. 75c.
A WALL PROTECTOR for placing behind wash stands.
A NEW SUPERIOR-SAVING MACHINE.
THE LITTLE GIANT CORN SHELLER, for \$1.50 by mail.
KNIFE SHARPENER that should be in every kitchen. 50c.
A CORN HUSKER that husks 400 bushels per day.
The best machine to CLEAN GRAIN in this world.
A NEW HON CARRIER, just out.
The cheapest BERRY BASKET ever made.
A HORSE RAKE that has no equal.
A SUPERIOR LUBRICATOR for Locomotives and Stationary Engines.
A NEW FIRE KINDLER for 75c.
We invite parties who feel interested in any of the above named inventions to call and examine samples or send for a descriptive circular of the article.

Agents Wanted.

Address **WIESTER & CO.**, Patent Brokers, 17 New Montgomery street, San Francisco.

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 35 MONTGOMERY STREET, S. F.

The best, speediest, and surest method for you to obtain patents, file caveats, or transact any other important business with the Patent Office at Washington, or with foreign countries, is through the agency of DEWEY & CO., PUBLISHERS OF THE MINING AND SCIENTIFIC PRESS, SAN FRANCISCO, an able, responsible, and long-established firm, and the principal agents on this side of the continent. They refer to the thousands of inventors who have patronized them, and to all prominent business men of the Pacific Coast, who are more or less familiar with their reputation as straightforward journalists and patent solicitors and counsellors.

We not only more readily apprehend the points and secure much more fully and quickly the patents for our home inventors, but with the influence of our carefully read and extensively circulated journals, we are enabled to illustrate the intrinsic merits of their patents, and secure a due reward to the inventor, besides serving the public who are more ready to give a fair trial, and adopt a good thing, upon the recommendation of honest and intelligent publishers.

To Obtain a Patent.

well-constructed model is generally first needed, if the invention can well be thus illustrated. It must not exceed 12 inches in length or height. When practicable, a smaller model is even more desirable. Paint or engrave the name of the article, and the name of the inventor, and his address upon it.

Send the model (by express or other reliable conveyance), plainly addressed, to "DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, SAN FRANCISCO." At the same time, send a full description, embodying all the ideas and claims of the inventor respecting the improvement describing the various parts and their operations.

Also send \$15 currency, amount of first fee of the Government. The case will be placed on our regular file, the drawings executed, and the documents made up, and soon sent to the inventor for signing.

As soon as signed and returned to us with the fees then due us, it will be sent straightway to the Patent Office at Washington.

When the invention consists of a new article of manufacture, a medicine, or a new composition, samples of the separated ingredients, sufficient to make the experiment (unless they are of a common and well-known character), and also of the manufactured article itself, must be furnished, with full description of the entire preparation.

For Processes, frequently no model or drawings are necessary. In such case, the applicant has only to send us an exact description, and what is desirable to claim.

For designs no models are necessary. Duplicate drawings are required, and the specifications and other papers should be made up with care and accuracy. In some instances for design patents two photographs, with the negative, answer well instead of drawings.

For further information, send a stamp for our illustrated circular, containing a digest of PATENT LAWS, 112 illustrated mechanical movements, and HINTS AND INSTRUCTIONS regarding the RIGHTS AND PRIVILEGES of inventors and patentees, which will be furnished post paid. Also a copy of NEW PATENT LAW of 1870.

DEWEY & CO.,

24v25-1f

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Sellers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco

Nevada Metallurgical Works.

Cautions Against Fraud.

The success of this most delicious and unrivalled Condiment having caused certain dealers to apply the name of "Worcestershire Sauce" to their own inferior compounds, the public is hereby informed that the only way to secure the genuine is to ask for LEA & PERRINS' SAUCE, and see that their names are upon the wrapper, labels, stopper and bottle.

Some of the foreign markets having been supplied with a spurious Worcestershire sauce, upon the wrapper and labels of which the names of Lea and Perrins have been forged, L. and P. give notice that they have furnished their correspondents with power of attorney to take instant proceedings against manufacturers and vendors of such, or any other imitations by which their right may be infringed. Ask for LEA & PERRINS' Sauce, and see name on wrapper, label, bottle and stopper.

Wholesale and for export by the Proprietors, Worcester; Crose & Blackwell, London, &c., &c., and by Grocers and Oilmen universally. 15v24-1f

GOOD WORDS

—FOR THE—

PAIN-KILLER.

We can confidently recommend the Pain-Killer.—[Toronto Baptist.]

It is the most effectual remedy we know of for Aches, Pains, fever wounds, &c.—[St. Johns News, P. Q.]

We advise that every family should have so effectual and speedy a Pain-Killer.—[Amherst N. S. Gazette.]

Our own experience is that a bottle of Pain-Killer is the best Physician a traveller can have.—[Hamilton Spectator.]

For both internal and external application have found it of great value.—[Chris. Era.]

A medicine no family should be without.—[Montreal Transcript.]

Could hardly keep house without it.—[Ed. Voice.]

Should be kept in every house, in readiness for sudden attacks of sickness.—[Chris. Press.]

No article ever obtained such unbounded popularity. [Salem Observer.]

One of the most reliable specifics of the age.—[Old North State.]

Its power is wonderful and unequalled in relieving the most severe pain.—[Burlington Sentinel.]

An indispensable article in the medicine chest.—[N. Y. Examiner.]

It will recommend itself to all who use it.—[Georgia Enterprise.]

Is extensively used and sought after as a really useful medicine.—[Journal, St. John, N. B.]

No medicine has acquired such a reputation; it has real merit.—[Newport Daily News.]

One of the most useful medicines; have used it and dispensed it for the past twenty years.—[Rev. Wm. Ward, Aseam.]

The most valuable medicine now in use.—[Tenn. Organ.]

It is really a valuable medicine, and used by many physicians.—[Boston Traveler.]

We always keep it where we can put our hands on it in the dark, if need be.—[Rev. C. Hubbard, Burmah.]

One of the few articles that are just what they pretend to be.—[Brunswick Telegraph.]

In my mountain travels no medicine is of so universal application as Pain-Killer.—[Rev. M. H. Bixby, Burmah.]

The Emma Mine.

The Emma mine, in Utah, is probably the best known American mine abroad. The circumstances of its sale, the immense sum paid for it, etc., are familiar to all interested in mining matters. Lately the mine has ceased paying dividends and the stock has fallen to one-half its par value. On the success of this mine depends in a great measure, the future of Anglo-American mining, for snob is its position, should failure ensue, small support will again be extended to American mines on the London market. In view of these facts the annual report of the directors of the company will be read with interest. It is as follows:

"In presenting to the shareholders the balance sheet for the year the directors have to express their regret and disappointment that the result is so much less favorable than until very recently than they had reason to anticipate. There have been paid to the shareholders 13 monthly dividends, amounting, including income-tax, to 193,532.5s. 2d.; while on finally making up the accounts to the end of December, it turns out that the funds available for that purpose only amounted to 185,657.13s. 7d., leaving a deficiency of 7,874.5s. 7d., from which it appears that if a full balance-sheet could have been made out in time (which was impossible) the thirteenth dividend would not have been paid in full, although remittances for the payment of the dividend having actually arrived, and the output at that time being sufficient, the directors had no ground for withholding payment of that dividend, or for anticipating difficulty in continuing regular payments.

The directors have, throughout the year, given the shareholders all the information they themselves possessed, and if at times it has been tardy or insufficient, some allowance ought to be made for the fact that the mine is situated in a sterile region of difficult access and 5,000 miles away. It is needless to do more than to refer to the chief causes of disappointment in the result of the year's operations. The disastrous flooding of the mine in June, the consequent caving in of the great chamber and blockade of the tunnel, caused many weeks' entire loss of work, deficient output for a longer period, and greatly increased expense.

This unforeseen misfortune was aggravated by the breaking up of the Cañon road, by the hostile action of the Illinois Tunnel Company taking armed possession of the only accessible part of the mine, and consequent prolonged litigation. It was impossible for the directors to foresee or avert any of these events; but notwithstanding the stoppage, the serious results of which were only gradually ascertained, the reserve on hand enabled the directors to continue the monthly dividends, which indeed they did not consider themselves at liberty to withhold, and after work was resumed they believed the assurance of those in charge that the arrears of output would be very quickly made up. In quantity this was so, but unfortunately the ore obtained since the flooding, and partly owing to the flooding, has proved of lower grade than previously, and fallen short in money value, while the expense was much greater than before, thus largely reducing the margin of profit.

Owing to the time it takes to get the monthly accounts from Salt Lake the directors were long in becoming fully aware of the falling off in value of the ore, but they believed the increased quantity would compensate for this, and that there would be no interruption of dividends. On 19th Nov. Mr. Hussey telegraphed: 'Will increase yield to 100 tons daily during week, also raise rich ore from the bottom,' and he also sent Mr. Park, on 22d Nov., the following estimate of probable quantities to 1st Jan: 'Will get out by 1st Jan. 70-oz. ore, 2,500 tons, which will net me say 50s. per ton, or 160,000 dols; also 350 tons rich ore, which from samples we may call 300 dols., or 105,000 dols., making a net earning of 265,000 dols. from now to 1st Jan.' (over 48,000l.). It was only on 19th Dec. that a telegram from Mr. Park (who acts as the company's agent and banker in New York) informed them that in a whole month only 20,000 dols. had reached him, and it became evident that the January dividend could not be paid, and of this the shareholders were at once informed.

"The small deficiency in the balance-sheet at the end of the year would, however, have been of little importance if the output had now reached a satisfactory amount, or if the prospects of it doing so were immediate. There is, however, still much of the winter to come, and the accounts from the mine tend to show that the rich ore in the deep level is less in quantity than was expected, and indicate changes in the quality of the ore, rendering much more selection necessary, and therefore greater expense and less output. Much of the ore, although retaining its average quantity of silver, is deficient in the proportion of lead stipulated for in the existing contracts, which were entered into with a view of maintaining a regular dividend, and seems taking more the character of ore for 'milling' than for 'smelting,' requiring a different treatment for its reduction, and therefore a different market. This may not cause loss, but, if continued, it is likely to create considerable inconvenience and perhaps delay; but by last advices it is stated that a contract has been made for the sale of 2,000 tons of this class of ore. It is fair to remark here, however, that the greater part of the mine remains unexplored, and that

besides existing reserves, the second-class ore, estimated by Professor Silliman at 8,000 tons, to which additions have since been made, still remains on hand, and will be available as soon as the best mode of treating it is ascertained. Mr. Husey having expressed a strong wish to be relieved, on account of his own business requiring all his time, the directors have been looking out for a man of experience and ability, and at the same time with thorough knowledge of mining; and they have engaged Mr. George Attwood, who has been most highly recommended to them, and who has already started for Utah to fill the post of resident manager. He is instructed, on his arrival, to send full information as to the condition and prospects of the mine, and to push explorations vigorously.

"The directors are of opinion that the shareholders are prejudiced by the very speculative character that attaches to their stock. They believe that the monthly dividend and the weekly telegram have a good deal to do with that. The monthly dividend clearly cannot be kept up steadily without a large cash reserve, and this, so far, the directors have failed in attaining. They recommend the following change: That instead of an interim monthly dividend of stated amount, interim dividends be paid from time to time of such amount as the directors find themselves in a position to pay. The directors have passed a resolution among themselves that their fees be reduced to one-half their present amount, with the addition of a commission of one per cent. on the net profits; but in no case shall the remuneration exceed the amount provided by the articles. They have made this change because they think the principle a correct one, that their remuneration should depend in some part on the prosperity of the company. The directors have lost the services of Percy Doyle, Esq., C. B., who has been obliged to resign on account of ill-health. Sir H. Selwin Ibbotson, Bart. M.P., and Sir Charles Wingfield, M.P., K.C.S.I., and C.B., have, however, joined the Board. At this meeting auditors must be elected for the ensuing year. Messrs. Kemp, Ford and Co., the present auditors, offer themselves for re-election."

Machinery.

IMPORTANT TO

Quartz Mining Companies.

IMPROVED PATENTED

Hardened Cast Steel Shoes & Dies.

The undersigned are prepared, at short notice, to furnish IMPROVED PATENTED HARDENED CAST STEEL SHOES AND DIES, for Quartz Mills of every pattern. This improvement supplies a want long needed by persons engaged in Mining enterprises.

They are more economical and cheaper than CAST IRON SHOES, as they wear from four to six times as long, and crush a greater quantity, as they retain their full diameter, never chipping from the edges. This, with the time saved in replacing worn and broken iron Shoes and Dies, and the great saving of freight to remote mills and mines, makes a vast difference in the cost of reduction of ores.

WE ALSO FURNISH
Cast Steel Tappets, Cams, Picks and Hammers,

Which possess the same advantage of Economy and Durability, and deserve the special attention of Miners and others engaged in quartz crushing.

The Superior Strength of these steel castings—the fact that they can be FORGED AND WELDED as easily as cast steel—their cheapness and great accuracy, as compared with forged iron—cannot fail to make them desirable for many purposes, where forged iron and steel have heretofore been used. Among such articles we mention:

ROLLING MILL CASTINGS.

Bevel and Spur Wheels, Guides, Spindles, Dies, etc.

AGRICULTURAL CASTINGS.

Reaper Guards, Plow Shares, Mold Boards, Plow Joint-cres, etc.

Anvils, Sledge, Vices, Masons' Hammers, Blacksmith Hammers, Mattocks, B. R. Frogs, etc.

And other articles requiring solidity and great strength.

DONKEY ENGINES FOR HOISTING,
Mining Machinery, Etc.

Persons giving orders will send diagrams and measurements of Shoes and Dies, etc., as above.

J. G. KITTREDGE & CO.,
No. 515 California street, San Francisco.
12-25-74Scaling and Foaming Prevented and
Fuel Saved.

Enquirers are respectfully informed that

WARSON'S AERO STEAM SYSTEM

Has been well tested, during three years, in England. Besides the above advantages, it greatly prolongs the life of Boilers, Tubes and Fire-boxes.

It is a cheap contrivance, and easily applied to any engine.

Illustrated Circulars, showing the appliance and describing its advantages, are sent to all applicants.

All who are troubled with Scale and Foaming may rely on this system of prevention—also on saving at least 20 per cent. of fuel.

RIGHTS for States and for individuals will be sold on liberal terms.

J. L. SANFORD,

General Agent for United States,

420 Montgomery street, San Francisco,

And Box 969, P. O.

Information Required to Give an Estimate
of Warson's Apparatus:

- 1.—Diameter of Cylinder.
- 2.—Length of Stroke.
- 3.—Number and Length of Boilers—Tubes or Flues.
- 4.—Distance of Boilers from Engine.
- 5.—Can Pump Piston be attached to Cross-head of Engine?

It can, however, be driven by any of the usual appliances that work the Water-Feed Pump.

These items will enable me to give a near estimate of the cost.

J. L. SANFORD, General Agent.

12-26-74

Notice is hereby given, that the copartnership heretofore existing between A. J. Severance, Charles W. Randall and J. Gus. Burt, under the firm name of "Severance, Holt & Co.," is this day dissolved by mutual consent. A. J. Severance, having purchased all the interest of his late partners, will continue the business of manufacturing and selling Diamond Drills as before, under the style of A. J. Severance & Co.

Dated San Francisco, Nov. 24, 1871.

Office, 316 California street. A. J. SEVERANCE,

JUST THINK OF IT—No Wood, no Coal, no Coal Gas, no Stove Pipe, no Chimney, no Smoke, no Ashes, no Dirt, no Wood Boxes, no Coal Scuttles, no Kindling Wood, but a Friction Match, and the Fire in Full Blast in Half a Minute!

OVEN HOT IN TWO MINUTES.

Steak broiled in seven minutes! Baked Beans in thirty minutes! The fire extinguished in a moment! And the house unheated!

It has no rival in all kinds of Cooking and Flat Iron Heating, and combines Economy, Convenience, Neatness, Safety and Durability! The Ladies Welcome it; a Little Child can operate it, and

ALL RECOMMEND IT.

Prices from \$6 to \$25, according to size.

ROCK DRILLS

— AND —

Air Compressors.

The Burleigh Rock Drills, which have stood the test
of five years' constant use at the Hoosac Tunnel, and
which are now in use in nearly every State in the Union,
as well as in Europe and South America, are unequalled
in efficiency and economy by any other Drilling Ma-
chine. They are of various sizes, and equally well
adapted to Tunneling, Shafting, Open Cut or Quarry-
ing, and will drill six to ten inches per minute in gran-
ite. They are driven by steam above ground. The Bur-
leigh Air Compressor is the best engine yet devised for
furnishing the "air motor" for the many purposes to
which it is now being used.
They are to be used on the St. Gothard Tunnel, Swit-
zerland; Tunnel 13 miles long. We refer to the follow-
ing gentlemen and works:

BROWN'S PATENT LAMP.

One of these Lamps, when placed at a distance of 200
feet from the bank, will light up a bank surface 250 feet
in length and 150 feet high, and to a much better ad-
vantage than any other light heretofore tried, and at an
expense not to exceed five cents per hour. Lamps
furnished at short notice.

Letter of Recommendation.

Mr. C. B. Brown—Sir: Your Patent Lamp for light-
ing hydraulic mines, which you sold to me in December
last, has given entire satisfaction, and far exceeds my
expectations, and I think it the best and cheapest light
ever used to light mining claims by night, and am sat-
isfied that I have saved three hundred dollars by the
use of it in the last mining season over pitch or any
other light of the same brilliancy; and I will also say
that if I could not get another lamp, five hundred dol-
lars would not buy it. Yours, W. D. APLIN.

Little York, Nov. 5, 1872.

For further particulars, address,

1e22-1f C. B. BROWN, Placerville, Cal.

HALLIDIE'S Patent Endless Wire Ropeway.

Covered by Numerous U. S. Patents.

IMPORTANT TO

Mining Companies, Civil Engineers, Contractors, Etc.

The system of transporting material, such as Ores, from the mine to the mill, Earths for embankments, Rock from quarries, etc., by means of steel wire rope, has been well tested and found more economical, advantageous and reliable than any other method of transportation; and to the annexed certificates in connection therewith I beg to call the attention of those interested:

EUREKA, Nevada, July 10, 1872.
T. M. MARTIN My dear sir: On your leaving for San Francisco, it gives me great pleasure to hand you my written acceptance of the HALLIDIE TRAMWAY put up by you upon our mine in Freilburg.

It is a perfect success, discharging ten tons of ore per hour with two men's labor. It is perfectly simple in construction, and, as far as I can judge, there is nothing about it to ever get out of order—nothing to wear out. While ours requires but about two thousand five hundred feet of wire rope, I can see no reason why the line could not be extended almost indefinitely with equally happy results. Again, the carrying capacity might be doubled or quadrupled if desired. After several weeks trial upon our mine, the unanimous verdict of all who have seen it is a complete, unquestioned success. If this can be of any service to you, use it in any way you think proper. Very respectfully, C. C. GOODWIN.

EMMA HILL CONSOLIDATED MINING CO.,
Little Cottonwood, Utah.
Superintendent's Office, Sept. 23, 1872.
T. M. MARTIN, Esq.—The Ropeway constructed by you (HALLIDIE'S PATENT) for the Emma Hill Consolidated Mining Company, has been built in a most substantial and workmanlike manner, and is at this time in splendid working condition. I most cheerfully accept the work for the Company, and recommend it to others wishing a sure and speedy transit for ores over places impracticable for wagon roads, etc. Respectfully,
L. W. COLBATH, Superintendent.

"The Vallejo works smoothly with the elevated wire tramway, which carries its load of ore as quietly and easily as if there was no winter or snow in the world."
Whatever the objections to wire tramways may be on account of their cost, I have seen nothing yet that even approaches them in the facilities they afford for moving ore at all seasons of the year."—Correspondent Utah Mining Journal, Alta. Jan. 8, 1873.

The Vallejo Ropeway.
The Vallejo Tunnel Company's Tramway in Little Cottonwood, built on the HALLIDIE PATENTED PLAN, is a complete success. It is between 2,300 and 2,400 feet in length, and is supported by timber. The fall in the distance is about 600 feet, and the wire rope, which is three-fourths of an inch in diameter, will safely and easily deliver one hundred tons in six hours. The machinery is automatic, loading and unloading the sacks or buckets. About one ton and a half can be sent down at one time. The stations are about two hundred feet apart, and the entire apparatus is strong and safe. As the wire rope is elevated about forty feet above the surface of the hill, the tramway can be worked all winter long, without the slightest trouble.—Utah Mining Journal, Salt Lake, Sept. 23, 1872.
Mining Companies and others desiring to negotiate for the erection of this system of Ropeway, can communicate with me personally, or through Postoffice Box 964.

A. S. HALLIDIE, Patentee,
112 and 114 California Street, SAN FRANCISCO.

WIRE ROPE

For hoisting from mines, transmitting power, ship rigging, etc., of all kinds and sizes, on hand and made to order.
Wire of all kinds and descriptions, furnished at lowest rates.
A. S. HALLIDIE, 112 and 114 California St.

THE GIANT POWDER COMPANY

Are now manufacturing besides the famous regular

GIANT POWDER, A NO. 2 GIANT POWDER,

Somewhat slower in its Explosion, which we recommend for

BANK BLASTING, COAL MINES,

AND FOR ALL SUCH WORK WHERE THE ROCK IS NOT VERY HARD

It is fully as safe as the other and evolves neither smoke nor noxious fumes when exploded.
Price, 50 Cents per Pound.

The sales of both grades increase very fast, which is the best proof of their superiority over other explosives.

BANDMANN, NIELSEN & CO.,

Number 14.

The Prall Steam Pump.

In these days of progress, speed and invention, machinery must take the place of hand-power, wherever such a thing is possible, and we are continually replacing one piece of machinery with another, if the slightest improvement is manifest. This is especially the case with pumps, of which there are probably more varieties and modifications than in any other class of machinery, with the exception, perhaps, of washing machines. In each of these inventions we try to simplify as much as possible the complications of previous articles. With simplicity of construction we attain not only that desirable object, cheapness, but gain space, reduce friction and lessen the liability of the machine getting out of order. One of the late inventions in the line of steam-pumps, which shows a wonderful simplicity of construction and operation is called the Prall Automatic Steam-Condensing, Vacuum and Force Pump, a cut of which is shown on this page. We recently saw this pump in operation at the Pacific Iron Works on First street in this city, where it can be seen by those interested.

The cylinders are made of metal, lined with wood. Into the upper end of each of these cylinders a small steam pipe is led from the boiler, the pipe being opened and closed by a simple two way valve, shown where the covering is broken away in the accompanying cut. A flat plate is placed opposite the mouth of the steam-pipe in the top of the cylinders to deflect and diffuse the steam as it enters. To the bottom of the cylinders is connected a single suction-pipe. Simple check-valves are placed on both the suction and discharge-pipes to prevent a reflow of the water passing upward. The valve-chambers are constructed with face-plates, which admit of ready detachment, so as to admit of removing and replacing the valves. A small injection-pipe communicates from one cylinder to the other, through the valve chest and throws a jet of water into the steam as soon as it has driven the water out of the cylinder. A vacuum is thus formed which draws the water from the suction-pipe and again fills the cylinder.

The automatic movement of the steam-valve, which admits and shuts off steam at the proper moment, is produced by means of a diaphragm of rubber, or of thin elastic metal, and connected with the valve by a simple rod (shown in the cut). This diaphragm is placed between two disks, which are slightly dished on their inner sides to admit of a play or movement of the center of the diaphragm between them, equal to the extent of movement required in the valve. This diaphragm is connected to the cylinders by water channels moved by alternate pressure on each side, thus admitting steam to one cylinder by downward movement and to the other by upward. An air-valve is placed in the upper part of each cylinder, admitting a little air into the top of the cylinder whenever a vacuum is formed.

In the operation of pumps thus constructed the pressure of the water in the cylinder when filled, bearing against the diaphragm, will press it up against its upper plate. The movement communicated through the rod to the upper valve is sufficient to open the valve wide. If steam be now admitted through the steam pipe, it will pass through the valve at the upper end and entering the cylinder will be diffused by the plate placed under the opening, into a stratum of air upon the water. The stratum of air serves to prevent all agitation of the water by the steam when it enters, so that it will spread

itself quietly and evenly over the entire surface and operate directly and as effectively as if upon the piston of an ordinary steam pump. The very thin film of air being instantly heated at the first contact of the steam, all further condensation of the latter is entirely prevented and the full pressure of the steam is brought to bear upon the water, to force it out of the pump through the discharge-pipe, noiselessly, and without friction, to any desired height, in proportion to its initial pressure. When, however, the steam, in expelling the water from

atmospheric pressure, the admission of steam being sufficient to cause a rapid discharge of the water thus elevated. Very small pumps made to operate in this manner with a low pressure of steam are constructed specially for agricultural purposes, to be used by farmers and stock-raisers, in connection with the boilers and cauldrons employed for steaming food for cattle, etc., thus enabling them with but a comparatively slight expenditure of fuel to raise all the water required for stock or irrigation.

As a mining pump it has a great advantage from the fact that there is no exhaust steam, the steam being condensed in the cylinders after it performs its work, so one of the great incon-

veniences of pumps in mines is removed. As there are no pistons, piston rods, stuffing-boxes, levers, cranks or fly wheels it requires no lubrication, and is not liable to be affected by mud, sand or grit of any kind passing through it. With no moving parts, other than the valves, it is not likely to need repair, and as the water flows quickly in and out of the cylinder, it is noiseless in operation. The one we saw at work ran beautifully, there being no intermittent action whatever. The simplicity of its construction and fewness of its parts are greatly in its favor, as it can be sold cheaply.

The pump requires a cubic foot of steam under a given boiler pressure to displace and elevate a cubic foot of water to a height due that pressure, and every foot of steam does double duty—by exerting a pressure to force the water out of the cylinder and by creating through its condensation a vacuum, the pressure of the atmosphere is utilized in filling the cylinders. It only requires a pressure of from one to two pounds of steam to raise the water to an extreme height of 30 feet, and for every foot of elevation above this point one-half pound of additional pressure is necessary. The pump is a model of simplicity in itself and it will repay any one interested in such things to go to the Pacific Iron Works and examine its operation. There is little doubt but that it will be extensively used in mining operations for the reasons above mentioned, and as it does not require an engineer to run it, being automatic, it can be

applied in many places where steam-pumps have not before been used. Small sized pumps of this pattern are made for independent boiler feeders, and will operate to feed boilers automatically, slowly or rapidly at any pressure.

A company has been organized to manufacture this pump, with the following Board of Trustees: Ira P. Rankin, A. G. Stiles, E. F. Knox, Eugene N. Riette and A. P. Brayton. The special manufacturing agency is at the Pacific Iron Works.

Work on Mining Claims to Prevent Forfeiture.

There has been some indecision among our mining community as to whether the amendment to the Mining Law of May 10th, 1872, which was introduced in Congress a short time since, had really become a law. Several papers have published an abstract of the amendment but were uninformed whether it was a law or not. The bill passed the Senate on the 11th of February, 1873, and passed the House on the 26th of the same month. That much came by telegraph; but whether the bill had been signed by the President or not was doubtful. We interviewed the Surveyor General and the Mineral Land Surveyor, but up to Thursday afternoon they had received no official notification that the amendment had become a law. A private telegram sent to Commissioner Drummond on Monday last had elicited no reply up to the time when we to press—Thursday night. We now find from a paper published in Colorado that the bill has really become a law and was approved on the 1st of March. It is as follows:

An act to amend an act entitled "An act to promote the development of the mining resources of the United States."

Be it enacted by the Senate and House of Representatives of the United States in Congress assembled, That the provisions of the fifth section of the act entitled "An act to promote the development of the mining resources of the United States," passed May tenth, eighteen hundred and seventy-two, which requires expenditures of labor and improvements on claims located prior to the passage of said act, are hereby so amended that the time for the first annual expenditure on claims located prior to the passage of said act shall be extended to the tenth day of June, eighteen hundred and seventy-four.

Approved, March 1, 1873.
Department of State, Washington, March 7, 1873.
(A true copy.) R. S. Chew, Chief Clerk.

The original law of May 10th, 1872, provides that on each claim located after the passage of the Act, and until a patent shall have been issued therefor, not less than \$100 worth of labor shall be performed or improvements made during each year.

On all claims located prior to the passage of the Act, \$10 worth of labor shall be performed or improvements made each year for each one hundred feet in length along the vein until a patent shall have been issued therefor; but where such claims are held in common such expenditure may be made upon any one claim; and upon a failure to comply with these conditions the claim or mine upon which failure occurred, shall be open to re-location in the same manner as if no location of the same had ever been made. Provided that the original locators, their heirs, assigns, or legal representatives, have not resumed work upon the claim after such failure and before such location. Under certain conditions prescribed in the Act, if a co-owner fails to do his share of work, the claim becomes the property of the other owner.

It looks something like "red tape" circumlocution to outsiders that this very important amendment—a measure involving thousands of dollars—has not been sent to the Surveyor General's office in this city. It is on this coast particularly, that the application of the amendment occurs, and still we have not been officially informed of its passage through the proper source. We have understood for some time that several parties had been formed in this city for the purpose of taking possession of certain claims upon which the requisite work had not been done, but their generous(?) efforts will now be in vain.

In reading the amendment carefully it will be seen that only claims located prior to the passage of the act of May 10th, 1872, have the benefit of the extension of time, since those located after the passage of the act are not mentioned.

the cylinder, follows it into the discharge-pipe, it is partially condensed, and the pressure on the under side of the diaphragm is so far reduced as to cause the latter to move and close the steam valve, whilst sufficient water is simultaneously withdrawn from the injection-pipe to complete the entire condensation of the steam, and produce a vacuum which will cause the cylinder to promptly fill from the suction-pipe. As soon as the cylinder is filled, the diaphragm will again move under the pressure thereon, steam will again be admitted, and the operation of the pump thus repeated. One cylinder is being filled while the other is being emptied, so the flow is continuous, and no intermittent action is apparent.

In one of the simplest adaptations of the pump for operating with steam at a pressure of from one to five pounds, the delivery-pipes are arranged entirely beneath the pumping cylinder, so that the water may discharge by gravity alone, or with slight additional aid. The condensation of steam admitted at this low pressure will produce a vacuum which will cause the pump to fill, even when placed at a height of 30 feet above the water, by means of

Utah Smelting Furnaces.

We make the following extracts from an article in the *Salt Lake Tribune*, on the "Smelting Ores of Utah:" "Upon the location of works depends, in a great measure, the economic reduction of the raw materials. The question of transporting the ore to the immediate locality of the fuel, or the transportation of the fuel immediately adjacent to the mines, has been unsatisfactorily solved, resulting, however, in the general adoption of the latter mode without any apparent economy. A number of causes operating together, render the erection of furnaces at the mines, in most instances, objectionable, while the transportation of the ores to the bituminous coal fields, or the timber-bearing lands where charcoal could be obtained, along the lines of the Central and Union Pacific Railways would produce no better results.

The solution of this problem is being effected by the erection of works along the line of the Utah Southern Railroad, between Salt Lake City and Sandy Station, where an economy of at least ten dollars per ton is obtained in the reduction of ores over either of the above mentioned modes. The concentration of an endless variety of ore by the system of narrow-gauge railroads inaugurated to reach the mines from the latter place, and the facility of obtaining a permanent supply of fuel by the lines of railway reaching charcoal and mineral coal fields, clearly indicate a greater economy in future manufactures by the erection of reduction works in this vicinity.

The next important consideration of the features which will establish the reduction of ores in Utah upon a permanent basis is

An Ample Supply of Fuel,

Efficient as well as accessible, and relatively cheap. Charcoal obtained from California at a cost of \$30 to \$40 per ton delivered at works in close proximity to the Utah Southern Railroad, must sooner or later necessitate the adoption of a substitute for this precarious and expensive article. There are abundant deposits of bituminous and ligneous coals in Echo and Weber cañons in this Territory, as well as the coal fields of Bitter creek in Wyoming Territory, contiguous to the line of the Union Pacific railway, from which coal can be laid down in Salt Lake City at prices ranging from \$7 to \$12 per ton.

The completion of the Utah Southern railroad through the Sanpete valley will place at reduction works along the line of this road an additional supply of fuel, from the bituminous coals of that region, which are of a highly inflammable and richly bituminous character, admirably adapted for reverberatory and refining as well as blast furnace purposes. The efficiency of mineral coal as fuel in the reduction of silver lead ores has been successfully solved in Europe, and its adoption in Utah must follow satisfactorily sooner or later as a matter of course, for whatever practical tests have been made by careful and experienced metallurgists tend to demonstrate that equal results are obtained in the blast furnace by using identical amount in weight of either charcoal or mineral coal. As data entering upon the bearings of this question there ought to be considered the calorific effect of the respective kinds of fuel, and paramount to the chemical constituents of any fuel are to be considered its physical properties, to wit, its power of carrying a burden—a quality especially essential in all metallurgical operations by the vertical blast furnace.

A feature of more than secondary consideration in the economic reduction of minerals is

The Construction of Furnaces.

The general adoption of the cupola blast furnace in the reduction of argentiferous galena and carbonate lead ores, largely predominating in many of the mining districts of Utah, may be regarded as sufficient proof of its superiority in practical metallurgy, notwithstanding many features of primitive simplicity exist in the general construction of our furnaces. It must be borne in mind, however, that for the production of crude bullion by cupola blast furnaces but a few elements are required, viz., charcoal, coke or coal, as fuel, and iron, limestone or other suitable substances, as flux, and upon the economical combination of these substances and the improved form of furnaces depends the quality and profit to be derived from this manufacture; but in this branch of industry, as well as others of importance and value to the human race,

Waste,

The great destroyer of man's fabrics, thrusts in its ruthless hand to curtail some profit in the enjoyment of the product of skill.

To overcome existing defects in this branch of industry the attention of many minds is engaged, and the ingenuity of not a few is endeavoring to solve it. Prominent among the devices proposed are. 1st. The adoption of a heated air blast. 2d. A sufficient quantity and pressure of atmospheric air. 3d. The application of oxygen to the zone of fusion.

The Introduction of a Heated Air Blast

To the reduction of lead ores in the cupola furnace may be considered an experiment in Utah, as only one furnace has been erected having in view the adoption of that important auxiliary, and from which no practical tests have been obtained so far as establishing its efficiency.

In the absence of any practical results, as data bearing upon this question, a few features in favor of its superiority and economy may be cited. In the reduction of iron ores the introduction of a heated air blast having been followed with economy in the production of crude pig iron, its application to the metallurgy of silver-lead bullion would follow satisfactorily, as a matter of course. Although cold air may support combustion in the same ratio as heated air, it does not follow that in metallurgical operations like results would be produced, neither can the supposition be sustained that deleterious chemical changes are produced by the addition of calorific air, as the relative proportions of oxygen and nitrogen in cold air are not altered when heated, and whatever elements exist in cold air are maintained to the same extent in the heated.

The superiority of the heated blast in metallurgical operations consists in the expansion of its volume, producing a more perfect combustion in consequence of the enlarged surface presented by the atoms of oxygen for combination with the carbon of the fuel. This involves a supposition that atoms of oxygen are expanded during processes of combustion.

The economy of heated air consists in the volume of heat carried into the furnace in the ratio of its temperature and pressure when introduced, as well as the economy with which it is produced. To those who do not possess a practical knowledge of the production of heated air for furnaces, it may be well enough to state that the gases usually escaping from the furnace can be utilized in the combustion chamber of the heating oven, as fuel to produce the desired temperature, and could be easily applied to furnaces already constructed. By the combustion of the escaping gases the minute particles of silver and lead would be liberated and deposited in the oven, and the gases usually considered unhealthy for workmen would be purified to such an extent as to form a sanitary provision to the works.

The admission of the air blast upon the zone of fusion, its volume and pressure, are usually considered questions of importance in practical metallurgy. Apparently the volume of air introduced into the blast furnaces of Utah is not projected with a relative pressure. This opinion is supported by two facts, namely: (1st), the general adoption of the rotary blast engine from which a maximum of three-fourths of a pound pressure is obtained, but in practice, however, seldom maintained; (2d), it is a fact well established that a volume of air projected into the furnace at a relatively low pressure creates a zone of fusion on the circumference of the column of material to be fused, while a relatively high pressure would maintain a sphere of fusion in the center of the column instead of its circumference, thereby effecting a more complete reduction of the ores exposed, and saving the fire-proof materials of which the furnace is constructed from the rapid wear to which it is subjected by the low-pressure air-blast. It is also well known that combustion in its chemical action is oxidation, and its mechanical concussion. It, therefore, seems apparent that the force with which the atoms of oxygen are projected upon the carbon of the coal are of paramount importance to an economic metallurgy."

Discovery of Relics of an Ancient Civilization.

Our sister Territories of Arizona and New Mexico will not in the future, as they have in the past, divide between themselves all the interest and glory of having been the theaters of a long-past civilization. Lincoln county, Nevada, steps to the front in claiming an equal share of such notoriety, bringing, in substantiation of her claims, hieroglyphic stones, figured pottery, stone implements of husbandry, etc. Day before yesterday, on the line of the Pioche and Bullionville Railroad, on the foothills about half way between the two places, relics of a by-gone civilization of these kinds were unearthed. Before us are fragments of the pottery, which can be inspected by those feeling a curiosity in the matter. They are composed of a gray substance, and figured with indelible coal-black colors. The figuring is regular, and as plain as the figures on porcelain just taken down from a merchant's shelf. We have not seen any of the stone implements. The curiosities were found on a level formation, about three feet beneath the surface, which undoubtedly had been constructed for a floor. The discoverers were excavating gravel to level up the railroad track when they struck upon the interesting depository. The spot is just beneath an overhanging point of rock, on which have been carved hieroglyphical characters in profusion, the majority having been obliterated by the erosions of time.

Further developments may disclose relics still more interesting.

It would seem that the ingenious race who manufactured these specimens of art should have known something of the immense silver deposits in the hills, at the base of which they had their habitations; but if they were workers in the precious metals the evidences have yet to be discovered.—*Pioche Record*.

GRAVEL DIGGINGS.—Parties in Virginia City are making arrangements to prospect some placer diggings known to them and situated somewhere in the Sierra Nevada Mountains south of Lake Tahoe. They are only waiting for the disappearance of the snow from their claims, when they will commence operations.

Mineral Resources of Costa Rica.

The name of Costa Rica implies wealth. To be entitled to the appellation of rich, a country must have possessed some peculiar advantages, and as at the time when the Spaniards gave the names to the countries they conquered, agriculture was only a secondary consideration; it must have been to its immense mineral resources that the country which now possesses that title owes its distinctive appellation. From the far north to the extreme south, the western coast of America abound in mineral wealth. The chains of mountains, which, in broken ridges follow its course over some great fissure in the earth's crust, are full of them. Metals of different kinds have been projected upwards into the masses of quartzose and basaltic rocks of which they are composed, and intimately mixed with the materials that were ejected at the same time, constitute now the rich lodes which have rendered so many districts famous in mining history. Distant, however, in many cases from the coast and from those modern appliances which speedily make them render up their treasures numberless mines of inestimable value, continue still undeveloped, and nothing often remains to tell of what in bygone times Spanish enterprise attained, but the mere empty name indicating the otherwise forgotten fact. Such is the case with Costa Rica. At the period of its conquest, the Indians possessed the precious metals in abundance, and the Spanish adventurers who subdued the Territory, reaped great spoils from the vanquished. A highly-favored and flourishing agricultural colony speedily sprang up, and this portion of Central America was one of the most promising possessions Spain had in the new world. The danger, however, from the bucaners, the disorganized condition of the mother country, with the consequent court intrigues and the more facile connection of other spots with the old world, together with a variety of conspiring causes, led to its later abandonment, and so great was the apathy of the Government, as also of individuals, that even the very existence of these precious metals which had made it famous was almost forgotten.

Years rolled on. A few Indians and a colonist here and there collected gold. A memory of the past was thus kept alive; but it was not till the end of 1821 that a poor man, called Nicolas Castro, opened the first gold mine since the time of the conquest. The success which attended his operations speedily induced others to follow in his footsteps, and as they were equally fortunate, a mining district sprang into being in a few short months. Since that time gold mining has been pursued in many of the mountainous parts of the Territory of the Republic, but as the means of those engaged in it has been very limited, and their knowledge still more so, the legitimate results have never been arrived at. The rude machines used for stamping, and the inadequate system of amalgamation pursued, entail a loss of more than half the precious metal with a still greater loss of the mercury. Yet even with all these disadvantages, large profits have been made, and large quantities of gold extracted.

Travelers who have visited the country have invariably expressed their surprise that, with rude methods employed, and the careless manipulation of the native miners, such results should have been obtained. They have wondered that, treated as it is, the auriferous quartz could have been made to give up its treasures, and whilst doing so have deplored that European capital, European energy and European skill, should not have been brought to bear on so rich a field instead of being turned to other and less profitable quarters. Nearly fifty years ago it had first attracted their attention, and twenty years later Mr. J. L. Stephens speaks in his work on the country with undisguised admiration of its wonderful richness. The lodes or mineral veins run regularly north and south, in ranges of greenstone porphyry, with strata of basaltic porphyry, and average about three feet in width. M. Peralta, a member of the Geographical Society of France, writing about the resources of Costa Rica in 1871, says—"The mineral deposits from one of the greatest sources of the wealth of Central America and the State of Costa Rica need fear no rivalry in this respect, either with California or New Holland. Gold, silver, copper, iron, nickel, zinc, lead, coal, marble, etc., are to be found in abundance in the bowels of the earth, or in the titanic gorges of the Cordilleras; but up to this time gold, silver and copper are the only ones which have been worked. Amongst the gold mines, those of the Ciruelitas, belonging to Mr. Carlos Giralt, and those which are worked by the Monte Aguacate Company, have given the most satisfactory results. From the above statement it will be acknowledged that Costa Rica—to use the language of M. Kaltrunner—is destined to a brilliant future, and will become one of the great Eldorados of the modern world."

A most important consideration in gold mining, to which the discoverers of new mining regions do not always pay sufficient heed, is the character of the climate of the district in which the mines are situated, combined with the facilities for obtaining an adequate supply of labor. It is in this respect that Costa Rica is as highly favored as she is in the extent and value of her unwrought mineral treasures. The climate in the vicinity of the mines is cool

and healthy all the year round. Labor is abundant and not too costly, the pay of an ordinary workman, including provisions, being 6l. monthly. Moreover, the miners generally work by contract, so that an exact estimate of the work to be performed can easily be made; the usual price per yard in ordinary ground is 24s. Taking all the circumstances into account—such as the proved richness of the Costa Rica mines, the facilities for working them in a manner which will largely increase their productiveness—there is a strong probability of the company which has been formed to work them proving a gratifying success to all concerned. English investors have had warning against trusting implicitly to the statements made with regard to mines in the United States, and it is now no small recommendation of any new mining district that it is entirely removed from the influences which so prejudicially affect American mines.

Unlike the United States of America, Anetolia and Brazil, Costa Rica is almost a virgin field for legitimate European enterprise of this nature. The native miners are unable to avail themselves of the improved machinery and modes of working; which are only attainable by the outlay of a considerable capital and of an experienced organization, and hence they cannot derive the benefit of that extension of which the mines are so fully capable. So great indeed is the scarcity of capital, and so exorbitant the ordinary rate of interest in the country itself, that the execution of all industrial enterprise, and even of public works, involves onerous pecuniary sacrifices.—*Mining World*.

Montana Mining Prospects for 1873.

The mining prospects were never better for a prosperous mining season in Deer Lodge county, says the *Independent*, than at the present time. It is true that the amount of gold taken out will probably be less than that of last year. There will be plenty of water during the season—the deep, solidly packed snow on the mountains insures this—and, as a general thing, the mines will average about the same as last year. Therefore the prospects for the mining community are very good. Laborers will also find profitable employment in the mines and on ranches, as there will be a general scarcity of laborers of all kinds, and next fall will find miners and laborers better off than ever before at the close of a mining season. The cost of living is now so much reduced that a laborer at \$5 per day can save as much money per month now as he could when he was receiving \$7 per day for his labor. In fact the great reduction that has been made in the price of water, mining tools, labor, etc., justifies mine owners in working ground with profit that would not pay heretofore. It is claimed by men well posted in such matters that there are acres of ground in this county that will pay good wages, now that prices have been reduced. Laborers in Montana can get plenty of work and good pay; we know of no country where the supply of labor is not greater than the demand. In Montana it is the reverse. The demand during the summer months will be far greater than the supply. Many mines will go unworked and many ranches untill in consequence of the scarcity of labor.

OPAL DEPOSITS.—The *San Diego Union* makes the following statement:

Some time ago a man named Williams brought in town a number of rough opals which he professed to have found in the vicinity of the city. Two of these stones he left with Mr. R. R. Morrison, jeweler, to have cut; one of the two opals Mr. Morrison valued at about \$150, the other at \$100. Williams had a number of other opals in his possession which he refused to dispose of and took away with him to Texas, for which State he left shortly after leaving the two specimens with Mr. Morrison. He refused to divulge the whereabouts of the deposit, but alleged that there were plenty more in the same place where he found the specimens he had obtained and exhibited. Since then Mr. Morrison has carefully explored those localities in the vicinity of the city giving indications of the presence of opals. He states that he believes he has discovered the deposit, but is not at present prepared to make any revelation concerning its whereabouts or to take any steps toward securing the ground, as the land is in litigation, being covered by a disputed Spanish grant, and having about half a dozen claimants. He believes the deposit to be rich and extensive.

GREAT GYPSUM DISCOVERY.—About seventy-five miles south of Pioche, says the *Record* of March 19th, a discovery has been made of immense deposits of pure gypsum. They were found a few days ago, by Joseph Mayott, of this city. A fine specimen from the deposits is now before us. It is a white laminated mass, with satin lustre. Pure gypsum, such as we take the specimen before us to be, carries nearly fifty per cent. of sulphuric acid, the balance of its substance being lime and water, the former predominating. It is of volcanic origin, being the product of sulphur gases escaping and the line of decomposing lavas. In the Mammoth Cave, in Kentucky, gypsum is found in the form of rosettes or flowers, vines or shrubbery. Burned and ground it forms plaster of Paris. We cannot see any immediate source of wealth in these Lincoln county deposits; in the future, however, they may become valuable.

SCIENTIFIC PROGRESS.

Curious Effect of Light on Selenium.

Selenium is a substance that resembles and is allied to sulphur. It is found in connection with some natural deposits of sulphur, but it more commonly occurs in combination with metals, forming selenides. Selenium is less combustible than sulphur, burns with a blue flame, and emits a putrid horse-radish odor.

Mr. Willoughby Smith has been making a series of electrical experiments with selenium, and, at a recent meeting of the Society of Telegraph Engineers, London, he made known the following results:

The sticks of selenium were connected with platinum wire and hermetically sealed in glass tubes. The electrical resistance of some of the sticks was very great, others much less, and he was at loss to account for this lack of constancy, until, after various trials, he found that it was due to the action of light. When the sticks of selenium were shut up in a box as to exclude light, the electrical resistance was highest and remained constant; but when the cover was withdrawn and light was allowed to fall on the sticks, the electrical resistance diminished 15 to 100 per cent., according to the intensity of the light. The shading of the selenium by means of glass plates of different colors showed that the conductivity was altered in proportion to the interception of the light. These are very singular observations, and may lead to new and useful discoveries concerning the qualities of other substances, and the manner in which light and electricity affect them.

REMARKABLE TELEGRAPHIC FEAT.—Capt. J. H. Hills, a Vermont telegraphic operator, being recently on a snow-bound train where severe suffering was anticipated, without speedy relief, cut the telegraphic wires, took their ends into a car where they would be sufficiently warmed to admit of being readily handled, and by sticking the ends together was able to "call" the operator at one of the principal stations on the road. He then sent the following message:—"Trouble. Answer slowly. I am working without an instrument; I will receive your answer through my tongue."

Captain H. received the answer by putting one end of the wire above and the other under his tongue, and letting the electric current pass through it, when he was able to read by the succession of sharp and somewhat painful electrical shocks. His success was perfect, and he not only sent and received messages for the conductor, but for several of the passengers. The only ill consequences of the exploit was the total loss of taste which Captain H. suffered for several days afterwards.

UNCONTROLLABLE FIRES.—Much has been said since the great fires in Chicago and Boston, about the uncontrollable nature of great fires. A correspondent of the *Scientific American* suggests the following as, at best in part, accounting for the special phenomena attending such great conflagrations:—

"When steam is heated to 5072° Fahr., it is decomposed into a mixture of oxygen and hydrogen gases, and about 8,000 units of heat are made latent; and when the gases again unite, which they will do when cooled by contact with colder substances down to a point below 5072°, the 8,000 units of heat will again become sensible, the process being analogous to that by which 962 units of heat are made latent when water is evaporated, the same amount of heat being again made sensible when the steam is condensed.

In great fires there is always a great quantity of water in the burning materials, and the heat is doubtless above 5072°. The result would be that the mixed gases would be driven out of the fire and would recombine as soon as sufficiently cooled, exposing any building or other object upon which they might strike to the heat of an oxyhydrogen flame."

THE "NORTHERN LIGHTS" REFERRED TO ELECTRICITY.—As further evidence that the auroral display may be referred to atmospheric electricity the following telegraph experience is given:—Capt. Hillaan operator at Burlington, Vt., having found great difficulty, on a certain occasion, when the "Northern Lights" were unusually brilliant, in receiving his dispatches from New York, attributing the interruptions to atmospheric influences, disconnected his telegraphic batteries, and requested the New York operator to do the same, when he found a much more even current, and worked some time with the atmospheric current alone, without any connection or assistance from the batteries. As soon as the auroral display materially diminished, the atmospheric current also diminished, and he returned to the use of the regular batteries without further interruption; thus plainly establishing a direct relation of cause and effect between the aurora and the electrical conditions of the atmosphere.

OXIDATION OF ALCOHOL.—On shaking absolute alcohol in a flask of ozonized oxygen, for a few seconds, the alcohol becomes acid and acquires the odor of aldehyde. The irritating (oxidizing) action of ozone is very much greater than that of oxygen.

NECESSITY OF REST FOR PLANTS.—Those who carefully watch the influence of spring upon vegetation, will find that it means something more than the mere action of light and heat upon certain chemicals. Thus, a glass jar, placed in the window of a room that has been kept constantly warm, contained several small water plants which have lain dormant all winter, although the heat and light seemed to be abundant. Now, however, that spring has come, they are all starting up vigorously. We know that even in the depth of winter, flowers and fruit may be grown, if freely supplied with light and heat; but it would seem that in spring these agents, even though apparently not more intense, are much more efficient than in winter, and it is probable that much of this increased efficiency is due to powers inherent in the plants themselves; but which require periodical seasons of diet in order to develop their full influence upon the organism of the plant.

MINUTENESS OF SPECTROSCOPIC RESEARCH.—Our readers have already been made acquainted with the fact that the spectrum is capable of discovering the presence of the most minute quantities of any mineral or gas, the light of which may be submitted to its analysis by means of vaporization; but we presume they are hardly prepared for the announcement that it is also almost or quite as effective in detecting the presence of infinitesimal quantities of dark substances, by the absorption, rather than the inversion of their light. It is thus that foreign substances, such as deleterious gases, etc., are detected in blood. Dr. H. Rath says that it is thus perfectly easy to detect and ocularly examine the human blood in the stomach of a flea. This same may even be diluted with a teaspoonful of water without losing its property as human blood, if the insect has recently been dining from the person of a human.

HEAT AND DENSITY.—It is generally supposed that the softening action of heat is due to the fact that it forces the atoms of matter apart, and prevents that close adhesion which exists when the mass is cold. Thus red-hot iron is soft and easily moulded by blows, because the heat expands the metal, and thereby weakens the force with which the particles adhere. We might, therefore, suppose that the more dense any given material could be made, the harder it would be; but a singular instance, in which the facts are exactly the reverse of this, occurs in the case of steel, which, though quite hard when tempered, has less density than when nitempered. The truth is that many very plausible explanations are only so in appearance, and would be discarded, if we knew all the facts in the case.

NEW METHOD OF CLEANING GLASSWARE.—Dr. Walz sends the *Scientific American* the following description of his new method of cleaning glassware. The vessel to be cleaned is filled, or, if large, rinsed with a moderately dilute solution of potassium permanganate, the contact of the liquid being prolonged till a film of hydrated manganic oxide has been deposited; the solution is then poured away, and the glass vessel rinsed with strong hydrochloric acid. Chlorine is then formed, but not enough to cause inconvenience; and acting in the nascent state on the organic matters, it speedily converts them into substitution products, which are soluble in the slight excess of acid or water.

RESEARCHES ON THE ALCOHOLIC FERMENTATION.—Dumas in a long article in *Comptes Rendus*, concludes that neither the view of Liebig, that fermentation is due to "influence," nor that of Berzelius, that it is due to "contact," is correct. He regards it as a chemical change, caused by the vital force of the yeast. "If I consider the alcoholic fermentation as a chemical fact capable of measurement and of modification by chemical forces and agents, I do not the less recognize its direct and constant dependence upon the presence, the action, or, in a word, the life, of the cells of the yeast."

ABSORPTION BY PHOSPHORUS.—Red amorphous phosphorus, under the influence of solar heat, as does charcoal, has the property of absorbing many substances without acting chemically upon them, as rosaniline, iodine, sulphur. Pulverized phosphorus agitated in a solution of iodine in bisulphate of carbon or rosaniline in alcohol, absorbs the iodine or the rosaniline, leaving the solution colorless. These facts are published as the result of the labors of M. Testini.

BLEACHING BY TURPENTINE.—It is well known that turpentine generates ozone, and the fact has been used for bleaching purposes. The turpentine is violently whipped by dashers and the ozone is blown from the generator into the vat containing the paper stock or other goods to be bleached. How far this operation is successful we do not know, and only throw out the suggestion for some one to give it a trial and report the result.

THE MILLION DOLLAR TELESCOPE.—The project of getting up a great million dollar telescope, by private subscription, bids fair to be realized. We presume that Government will come to the aid, if necessary, in furnishing the last stipend that may be necessary to secure the construction of such an instrument. If possible, it should be completed and mounted at Philadelphia, ready for use at the coming Centennial Celebration.

IMPROVEMENT IN THE MANUFACTURE OF GLUCOSE.—It has been discovered by Mr. Krothe, that by adding a small quantity of nitric acid to the sulphuric acid, in converting starch into syrup, (glucose) he is able to save half the time required for affecting the conversion by the use of sulphuric acid alone. In preparing solid glucose the saving of time is much greater. The manufacture of solid glucose (grape sugar) has largely increased of late.

MECHANICAL PROGRESS.

Tempering Steel.

One of the most promising, profitable, and apparently excellent of these patented processes is that of Garman & Siegfried, owned by the Steel Refining and Tempering Company, Boston, Mass. Congress has appropriated ten thousand dollars to pay for the right of use in the government shops. It is said to impart an extraordinary hardness and durability to the poorest qualities of steel. The following description of the process is from Siegfried's specification, patent of July 16, 1871:

"I first heat the steel to a cherry red in a clean smith's fire, and then cover the steel with chloride of sodium (common salt), purifying the fire also by throwing in salt. I work the steel in this condition and while subjected to this treatment, until it is brought into nearly its finished form. I then substitute for the salt a compound composed of the following ingredients and in about the following proportions: One part, by weight, of each of the following substances: chloride of sodium, sulphate of copper, sal ammoniac, and sal soda, together with one-half part by weight of pure nitrate of potassa, said ingredients being pulverized and mixed. I alternately heat the steel and treat it by covering with this mixture and hammering until it is thoroughly refined and brought into its finished form. I then return it to the fire and heat it slowly to a cherry red, and then plunge it into a bath composed of the following ingredients in substantially the following proportions for the required quantity: of rain water, one gallon; of alum, one ounce and a half; of sal soda, one ounce and a half; of sulphate of copper, one ounce and a half; of nitrate of potassa, one ounce; and of chloride of sodium, six ounces. These quantities and proportions are stated as being what I regard as practically the best, but it is manifest that they may be slightly changed without departing from the principle of my invention."

TUNGSTEN STEEL.—Some experiments are described which do not tell as much in favor of this tungsten steel (Mushet's special steel) as those we have previously noted from time to time. A sample of the steel was prepared precisely in accordance with Mushet's process, and with all necessary precautions, but it was found that it would not bear forging at all well. A chisel made from it would not bear the blows of the hammer, and broke up into splinters. A knife which was forged for a planing machine did not stand nearly as well as a cast steel knife of exactly the same pattern. The tungsten steel appears to possess great hardness, with a fine scaly fracture, but is far too brittle for ordinary uses. These remarks are in almost direct opposition to those of Professor Heeron, who speaks very highly of the value of this steel for planing machines. Analysis of the two samples showed a certain difference in composition between that used by Heeron and that by Kick: the former containing 8.3 per cent. of tungsten and 1.73 of manganese; whereas the latter gave the mean values—Iron, 87.52 per cent.; manganese, 2.33; tungsten, 8.78; silicon, 0.76; phosphorus, 0.01; sulphur, 0.21; carbon, 0.41 per cent.; titanium, a trace. Total, 100.03.

NEW METHOD OF PLATING.—A very interesting invention, lately developed by Mr. Brownell, of Hartford, relates to the plating of metals with nickel, gold or silver. He puts a thin plating of nickel or gold or silver to other metals, and then melts it in, so that, while the surface is of the color and character of the plating, the latter so permeates the main metal that it neither scales nor wears off. Nickel applied to the linings of boilers, to the sheathing of ships, to the coating inside and out of gun and pistol barrels, prevents oxidation, lime incrustations, or any detrimental soiling, while it keeps the surface smooth, clear and bright. The expense of this method of plating is only a quarter of one per cent. additional; and if, as seems quite certain, it proves practicable on a large scale, this mode of coating coarser metals with finer will find new and larger applications.

NEW PREPARATION OF PAPER AS A BUILDING-MATERIAL.—An English company prepare a water-proof material out of paper-pulp, or any fibrous substance, by saturating it with ammoniated copper solution—a digest of copper scrap in concentrated ammonia. This treatment dissolves the fibres and renders the paper impervious to water. A number of sheets of paper are maintained on the surface, placed on each other, and thoroughly pressed. They thus are made to adhere firmly together, and are then fashioned into the various forms required. The product may replace corrugated iron for roofing, or it may be made into columns and flutings for internal decoration. It is said to be a very durable material even when exposed to air and rain.

A Lesson in Friction.

The following facts teach a lesson which shows how important it is that the utmost care and caution should be observed in relation to everything where human life and safety is involved:—The steamship *Saragossa* was lately put upon the ways at Baltimore, supposed to need only new caulking and copper. The caulkers got to work, and the seams between the planks were dressed out with the irons preparatory to driving in the new oakum. Imagine the astonishment of the caulkers when one day the iron, subjected only to a feeble blow, went clear into the vessel. A closer inspection resulted, and it was discovered that for a distance of eighty feet on each side of the keel, and beneath that portion of the ship where the boilers rest, planks which eight years ago were three and one-half inches thick were now mere boards and one-half inch in thickness. They were not worn-eaten, and to all appearances were as sound as when first spiked and bolted to the huge skeleton of the ship. And here is a lesson in the power of friction which is aptly illustrated. Beneath the boilers of the *Saragossa* it was discovered that particles of coal had dropped from time to time, and the mere motion of the vessel as she rocked at sea had shaken the loose pieces of mineral from side to side on the planks, and worn them to the thickness of boards used in the ordinary skiff, such as are used in our creeks.

MICA HEAD LIGHTS FOR LOCOMOTIVES.—The introduction of silvered mica reflectors into locomotive head-lights has proved a complete success. An engineer on the West Jersey railroad, who has been using them, says he can by their aid distinguish the features of a person at a distance of four hundred yards. They are now being tested on the Reading, North Pennsylvania, and other railways, with the most encouraging prospects as to their adoption on account of their economy, durability, efficiency and saving of labor. In case of accident they are but little liable to injury. A case is mentioned of a locomotive on the North Pennsylvania railroad, which recently exploded, and the smoke stack of the locomotive fell heavily on the lantern, completely demolishing it and sending the reflector almost double, when relieved of the pressure, it sprung back to its shape, and with the exception of the displacement of one or two small pieces of the silvered mica, it was uninjured; whereas had it been a metal reflector it would have required replating and bending, involving an expense of at least twenty dollars.

Why might not these reflectors be advantageously introduced in our hydraulic mines?

MECHANICAL WOOL CARVING.—Mechanical appliances for facilitating the carver's art are occupying much attention just now. Charring the depressions by passing blocks of wood underneath a heated roller so as to leave the unburned portions in relief, from which electro-types may be taken for printing, and the sandblast process are among the latest inventions in this direction.

And now we have a device by H. A. Lantaigne, of pans, which is highly spoken of by the European press. The wood, in this process, is passed between a bed-plate and a matrix cylinder, on the surface of which the design has been cut, so that it is pressed into the wood. The ease of this cheaply producing ornamental woodwork is apparent, and the invention has been pronounced by some, as one of the most valuable industrial products of the last ten years.

COKE FROM LIGNITE.—Mr. Henry Englemann, who has been experimenting largely with Wyoming coal, reports that he finds a good coke can be produced from it. His experiments have been made with a furnace capable of receiving half a ton charge. The interesting point in these experiments is the fact of obtaining a good coke from a coal that is regarded as an undoubted lignite—though a lignite of superior quality. If the experiments of Mr. E. are reliable, and capable of being made economically practical, the discovery will be of much value to many mechanics and many interests of that section of the country.

HARDENING BURNED STEEL.—For hardening the steel points of tools of boring machines, etc., when burnt, J. Jossi proposes the following method: 10 parts of tallow, 2 parts horn filings, 1 part sal ammoniac, 1 part pulverized charcoal, and 1 part soda are mixed together and placed with a piece of wood on the parts to be hardened, after they have been exposed to a cherry-red heat. The mixture dries under the influence of the heat, and the steel parts may be hardened again in the usual manner.

COMPLIMENT TO AMERICAN MECHANICS.—A recent English work on the strength of materials and structures contains a valuable series of tables, derived chiefly from experiments made at the British national engineering establishments at Chatham and Woolwich, by means of a simple and efficient machine for testing strength and elasticity, of American origin. This is a high compliment to the ingenuity of American mechanics.

A NEW PLATING PROCESS.—A gentleman at Hartford, Conn., has invented a new process of plating iron or any composition metal either with gold, silver, or nickel, the plating being so driven into the surface that it becomes a part of the metal itself. Experiments have been made on boiler iron at Colt's factory, with perfect success, and the Government is going to test the merits of the invention.

Assessments, Meetings, Dividends.

NOTE.—In the Stock Boards an assessment is delinquent thirty days from the date of levy, exclusive of that date. The dates given in this list are those of the mining offices.

ASSESSMENTS.—Stocks on the Lists of the Boards.

Chief East Extension.
Dispatch of the 31st says the ledge in the

latter part of this week we intend to cross-cut east from the extreme northern and southern ends of the north and south drifts on this level.

The ore worked in the west vein, immediately adjoining and north of the incline, has now widened out to 11 feet as we have raised upon it. The length of this body, as far as worked, appears to be about 25 feet. The opening in the engine winze, at the 11th station, shows a breast of ore 11 feet wide to the north, and to the southward of winze it has narrowed down to two feet in width. This ore is of good quality.

Huhn & Hunt.

Dispatch of the 31st says the pulp assays for the last two days run from \$33 to \$109 per ton. Will commence shipping bullion on Tuesday.

Imperial.

Letter of the 31st says the winze known as the Empire looks unusually well to day; no change elsewhere. Expect to make a connection with the north drift of the Yellow Jacket to night.

New York Con.

Letter of the 1st says the ledge is getting larger, and now covers about two-thirds of the bottom of the shaft and is not through yet. It dips to the east, and runs nearly north and south. Are in about three feet on one side. Sink the shaft 27 feet during last month. The rock is soft but has a little more water. Assays to-day give \$1.40.

Noonday.

The quality and quantity of ore have improved considerably since last report. Have run the drift about 6 feet since turning the direction to the east. The whole space of the drift is now in ore, and the proportion of first-class has largely increased.

Overman.

No change during the past week. The faces of the drifts are in about the same kind of rock, with the exception of the north drift, which has more quartz making in, and the ground is considerably softer. Have made 24½ in west drift, 23 feet in north drift, and 24 feet in south drift during the week. Since starting the blower the air has been good in all the drifts, and much better progress will be made in developing the 1,000 foot level. The water in the shaft and drifts is decreasing slowly.

O. H. Treasure.

Letter of the 27th says the incline shaft is down 208 feet, which makes the total distance from the surface 300 feet. Have started a drift at this point to run south on the foot wall, which will prospect the ground to the south line of the claim. At the Wheeler have suspended work on the south drift, and started north on the slip. This will prospect the ground toward the incline shaft at a depth of 500 feet from the surface.

Ophir.

Letter of the 27th says that the east crosscut from upraise, north mine, first station, is getting no harder ground and little progress is being made. The water is gradually decreasing. Winze, south mine, second station, shows an improvement, more quartz than usual being in sight. The north drift 1300-foot level, is going ahead well, but without any material change. There is no change to note in lower level.

Letter of the first says east crosscut from the upraise, south mine, first station, after passing through 40 feet of mixed ledge matter, is in hard porphyry, which they think will prove to be the east wall. A new body of quartz has been uncovered on the east side of the main south drift, second station, about 130 feet south of main north drift, which promises well, although the assays are low as yet.

Pioche.

Letter of the 24th says they received the final clean-up from the Magnet mill yesterday. Will have about \$4,000 from 54 tons of ore. Have the best of the ore on the dumps.

Letter of the 26th says the amount of bullion received from the Magnet mill for 54 tons 1,350 pounds of ore is \$3,814.75, about an average of \$70 per ton. Pulp assay \$121.17. The Floral mill will probably start this week. Car samples for the 24th, \$169.64; for the 25th, \$112.57.

Raymond & Ely.

Letter of the 24th from the Superintendent says the mills are running well, with about 1,200 tons of ore on hand. The roads are good, about 150 tons going down daily. Work in the mine is progressing well. Drift on eighth station is in 70 feet, west drift, 7th level, is in 73 feet, east drift 110 feet, no special change in either. In 6th level, west extension, there is some improvement. The stopes in the upper levels of this ground are yielding exceedingly well. Tracings about Panaca shaft are good and nearly completed.

Dispatch of the 31st says. "I shipped today, \$37,336." Previous shipments this month aggregate \$205,062—making a total for the month of March of \$243,391.

Savage.

The weekly report for the week ending on the 29th gives the following summary of operations: Ore extracted from the mine, 241 tons 1,900 pounds; ore shipped to the mills, 355 tons 1,900 pounds; on hand at the mine, 25 tons; average assay value of the ore, \$25.53. The ore came from the second station of the north mine.

Silver Peak.

Letter of the 28th says the ore breasts are still looking well—if there is any change it is for the better. Arogeting out all the ore that can be hoisted with the windlass. If the ore holds out as it is now there will be no trouble about making it pay. The Floral mill has not started up yet, but it will start soon, and we will then have the ore worked as soon as possible. A sample from the breast on the 24th gave an assay value of \$46.47. A sample taken from each tub yesterday as it was hoisted gave an assay value of \$155.73.

Union G. M. Co.

There was received on April 1st at the office in San Francisco from this mine, located in Howland Flat, 161 ounces of gold dust.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned:

California.

ALPINE COUNTY.

ALPINE.—Alpine Miner, March 22: The south drift in this mine is encountering bunches of ore, and it is said to be probable that the copper vein which crossed the main tunnel back of the ledge now drifted upon is in contact with the drift, as signs of copper are seen. The main tunnel is now running in very favorable ground for progress, and feeders of white quartz are becoming more numerous, indicating the approach to a ledge. The quartz is often of the character of that found on Boulder Hill in early days, which carried gold to such an extent as to render it profitable to work in an arastra.

GLANCE.—The mine is showing nice quartz and some good pockets of ore, but the main ore vein has not been reached on its dip by the perpendicular shaft; it is slow work going down by hand, but when below 75 ft., and we are glad to learn that the Co. intend soon to commence the erection of steam hoisting works.

EL DORADO.

ST. LAWRENCE.—Placerville Republican, March 27: There has never been a mine opened in the State that has paid so well right from the start and continued without a single break to increase in richness to the depth of 40 ft. and over, as has this mine. It is certain that the St. Lawrence has rock enough that will work from \$10 to \$15 per ton to run 30 or 40 stamps for at least a year, and feeders of white quartz are becoming so numerous that it is unreasonable to believe that it will last twice that long.

PACIFIC.—This mine in this city is probably equally as good as the St. Lawrence, and it is a misfortune to the community that it is in hands that will not allow it to be worked.

POCAHONTAS.—For several months this favorite mine rather lost prestige, but we are glad to learn that it is now making a splendid showing.

SHEPARD & WITTEN.—The mine is now down 30 ft. on their ledge, and the last rock taken out looks better than any before struck.

SHEPHERD AND WHITTON LEDGE.—Placerville Democrat, March 29: A few weeks ago we made notice of some handsome gold bearing quartz taken out by Shepherd & Whitton from a shaft they had commenced sinking on the ledge of a point just behind the Empire Office. It seems that they were operating at that point by the sufferance of the Church Society and only for temporary prospecting purposes, to test that portion of the ledge. Since our notice they have sunk something like 50 ft., obtaining ore of uniform excellence all the way, and now they are negotiating for right of way, etc., to start a tunnel from a lot on Coloma Street, near Main, running under the southwest corner of our office and striking the ledge after running northeasterly about 100 ft.

HUMBOLDT COUNTY.

HUMBOLDT REGISTER. March 29: A San Francisco company have 8 men at work on a copper mine in Pueblo district, 50 miles northwest of here, and are taking out some excellent ore, which will be shipped below for reduction as soon as the roads and weather will permit.

BOLIVIA DISTRICT.—Silver State, March 29: Reports from the copper mines from this district are of the most encouraging character. The ledge in the north mine and rich ledge have been discovered in the district within the last two weeks. Kellogg & Co., the owners of the principal mines in the district, and withal men of ample means, have concluded to open a road from Oresau to the mines and thence to Austin.

STAR DISTRICT.—The Krom Combination is completed. The machinery was started yesterday. The Le Soto mine is producing fine ore. About 10 ft. of the vein is antimonial sulphurets, which assays high in silver. Chunks of this class of ore weighing from 50 to 200 pounds have been extracted during the present week.

SILVER CROWN.—This mine is located on the eastern slope of Table Mountain, 8 miles from the Bolivia copper mines. It has been prospecting by tunnel and shaft about 90 feet to the surface. The ledge is about 5 ft. wide and carries from 4 to 8 inches of ore, principally black sulphurets, with horn and native silver, and assays from \$1,000 to \$4,000 per ton. It is situated in a limestone formation, from which it is separated by a "gouge" sometimes a foot thick. The ledge has been discovered on the surface 600 ft. from the tunnel, and appears to be a fissure vein.

FLORAL MINE.—The mine is getting to be the rage here now. Miners have been prospecting Cottonwood Canon, and struck "two bits to the pan and the bedrock pitching." Some have quit \$4 a day in the silver mine and gone to Cottonwood, expecting to make better wages working gold mines on their own hook.

KERN COUNTY.

DAMASCUS PLACER DIGGINGS.—Havilah Miner, March 29: A letter from Shurtner and Voegel informs us of new placer diggings. Their original intention was to work on the old claim of John Kupp, but finding it a "petered bill" they prospected and have just found good diggings within a few miles of Buys, where plenty of water can be obtained for four months.

MINING AT LONG TOM.—We learn from a friend who has lately returned from a trip to Long Tom, that H. Burdett is taking out very rich rock. A run at the mill which was lately cleaned up, paid \$30 per ton. The gold could be seen glittering in the ore as it lay on the dump. The expense of the run for the same time in the immediate vicinity is now opened with several hundred tons of the same kind of rock in sight.

NEVADA COUNTY.

INABO.—Nevada Transcript, March 27: This mine cleaned up its amalgamators last Saturday, after a run of six days, gold to the amount of about \$19,000.

GREEN MOUNTAIN.—This mine, which has a mill of only five stamps, cleaned up after a six days' run on Saturday, the net little sum of \$2,500 in gold—not counting sulphurets.

EUKEKA.—This mine after six days' run with ten stamps, cleaned up about \$10,500 worth of gold.

STATE LEDGE.—This mine (Perrin's) in six days' run, cleaned up \$1,200.

MONTANA.—March 28: This Co., at Willow Valley, has had about 100 tons of rock crushed, which paid at the rate of \$38 per ton. They have plenty more of the same kind of rock on the dump.

The old Leocompton is being worked, and the rock looks first rate.

The Gold Tunnel Co. have struck a fine body of rich rock, and the prospects are better than ever.

The Murchison mine continues to yield handsome returns. Negotiations are going on for the sale of all the claims on Selby Hill and Flat, and it is thought the sale will be made in time to put the claims in order before next fall.

Preparations are being made to resume work on the Manhattan, at Gold Flat.

INABO.—Grass Valley Union, April 1: The mill completed a month's run on last Saturday, the month consisting of 30 days. The 35 stamps of the mill were constantly run. The yield of gold for that time is about \$115,000. The expense of the run for the same time amounts to about \$35,000. Underground and above ground everything is in the most splendid condition.

EUKEKA.—The run, 24 days, gave a return of about \$50,000 worth of gold. Only ten stamps have been running during the time and the result is good. The last letter of the Superintendent to the Trustees says: "The bottom west drift shows a little water, and the ground is a little harder. No change in the east drift. The

ledge in the 6th level rises is 3 ft. wide, and the quartz looks well. The ledge in the intermediate shaft and stopes looks well."

STATE LEDGE.—This Co. made a clean-up of \$1,100 for the last two weeks—the aggregate for this month being about \$5,000—expenses for the same period not exceeding \$2,800. The ledge in the mine is large, and the dump is full—the rock coming out faster than the mill can reduce it.

DAMSK HILL.—This young mine is giving promise of a prosperous future. It is now down 114 ft., and the week amounted to \$6,000 or \$63.63 per lot. This crushing came from the 2d level, at the depth of 225 ft. Another crushing will be made in a few days of rock from the bottom of the mine, 315 ft. deep. The mine is looking well in the drifts and stopes, and the crushings are always good.

HOWARD HILL.—The shaft is down about 385 ft. deep, and from the bottom of it drifts have been run to the east and to the west. The east drift is in 146 ft., and the west drift is in 111 ft. In the west drift the ledge is 14 inches thick, is between two good walls and is therefore well defined. In the east drift the ledge is not so wide but has been steadily in ravine since the drift was started. The shaft is now down 114 ft., and the ledge is 14 inches thick. The ledge is now much softer than it has been since commencing the shaft, and it is believed the contractors will be able to make 8 ft. in 24 hours. A number of feeders of the main ledge have been cut the last 10 ft., some of which assay high. A good ore body must be near. Developments in the old works continue satisfactory.

MANHATTAN.—The location of this company's claim is not far from the Pittsburg. It is a consolidation of the claims of the Krom and I. O. T. Co. and embraces 3,000 ft. of claim. It is a local mining company, the stock being held in Grass Valley and Nevada. The tunnel will be about 700 ft. in length, and the backs above the tunnel about 110 ft.

GRASS VALLEY NEW MINING CO.—Work has been suspended on the Imperial ledge owned by this Co. for the last month, owing to water, but the Trustees have not concluded a bargain for a complete pumping and hoisting rig, which they expect to have in full operation by the first of May. During the interim they have purchased an extension of the Kentucky Ledge, which they are at present sinking on, with very flattering results, having struck a fine ledge 20 inches thick, which promises to be a paying investment.

GRASS VALLEY.—This mine, situated on Oshoroa Hill, has been turning out during the past month as it did in times past. The mill is a five-stamp mill and in 18 days' run it cleaned up \$6,500 including \$81.40 received from sulphurets. For the past two weeks the rock has been piling at the rate of from \$50 to \$60 per ton. The mine is still looking well in both the north and south drifts.

KURTZ OF MALTA.—The shaft is down 97 ft. and a drift on the ledge for the distance of 60 ft. has been run. The ledge is well defined and is very large. The quartz is heavily charged with sulphurets.

BROWN SOUTHERN HYDRAULIC.—Situated on the head waters of Squirrel Creek, west of the town. They have done well this winter. Three men have been employed, and in the month of January and February gold to the amount of about \$2,000 was taken out. The water comes but little so that the profit is great. They have pitched up one piece of gold which was worth \$120. They frequently find these chips.

NORTH STAR.—The new shaft is down 270 ft., and is in beautiful rock showing gold through the whole depth.

KENTUCKY GOLD MINING CO.—This company is now fully prepared for work and is at present not doing for machinery capable of thoroughly prospecting this mine.

EMPIRE.—They have a great quantity of quartz broken up and awaiting crushing. The mill has been idle because the wood to make steam did not hold out. The ore is splendid.

NEVADA CRY DISTRICT.—The Providence, on Deer Creek, just below the City and the Nevada, on the same ledge, are showing splendid ore. The Nevada is taking out rock which will mill in the neighborhood of \$30 per ton, not counting sulphurets. These two mines are on the same ledge, have the same character of ore, and have drifted together under the head of Deer Creek.

The Henge, about 200 yards below the Providence and Nevada, is showing work and is at present not doing for machinery capable of thoroughly prospecting this mine. Rich specimen rock has been lately taken out of the shaft.

The North Potol, situated on Gold Flat, and not far from the once-famous, but now idle, Pittsburg, is in very fine ore, with ledge 4 ft. in thickness.

The Gold Tunnel mine is taking out good rock. **EXTERMINATE GRAVEL.**—This mine is located at Buena Vista, about 8 miles from Grass Valley. The Co. has been operating about 3 years, seeking to develop the riches of the gravel channel of the "slide." A perpendicular prospecting shaft was at first sunk, but the use of this has been dispensed with, and an incline put down 230 ft. from the bottom of which the main drift runs into the hill 1,300 ft. At various points side drifts and "rises" have been made for prospecting purposes, and recently a body of gray gravel has been opened near the end of the main drift, which is from 2 to 2½ ft. in depth, and pays from \$7 to \$8 per ton. The extent of this body of gravel is yet unknown, but the daily developments made upon it encourage the belief that it will prove extensive. The main shaft runs underneath the gravel, and to strike the deposit of "rises" are made, and the gravel sent down to the cars through chutes. The mine is strongly timbered throughout. The incline is a good piece of workmanship, having 2 tracks for cars, and a pump and gangway. An 8-inch pump is used, but the demand is light upon it, as the mine is remarkably dry. Recently the company have erected a 10-stamp mill in connection with their hoisting works. The stamps are 850 lb. weight, and are capable of reducing 60 tons in 24 hours. The mill has been in operation but a few days, and the first regular clean-up was made on Saturday last, after five days' run, the result being 84 ounces of amalgam, worth about \$700. The Co. have expended \$40,000 upon the mine and machinery, and although they have levied 19 assessments they have never sold out a delinquent.

PLACER COUNTY.

MINING ITEMS.—Placerville Herald, March 29: S. H. White and partner, the mine located near the Wells mine. They have a shaft down 20 ft., and at this point found 4 or 5 pieces of ore this week, all showing free gold and an abundance of good sulphurets. There is a system of veins in the bottom of the shaft, all close together, and it is believed that at a further depth of 30 ft. they will all center in a heavy, rich ledge.

S. H. WHITE.—We have seen some fine specimens from this mine, in the edge of town, bearing free gold, and the character of the rock and sulphurets are such as is only found in paying mines. The shaft is down near 180 ft., and on a good, well defined ledge.

YOLO MINE.—This is a rich strike, made a short time ago, near Temperance Flat, 3 miles northwest of here, from the surface, and was then sold. The new owners are pushing a shaft down with commendable energy. They have a large, well-defined ledge, rich in sulphurets, carrying free gold, that prospects well.

ABURN.—This mine, alias Calif-pasture, alias Dillon, is being prepared for a good summer's work. They are nearly 200 ft. below the surface, and have cut very rich ore in various drifts.

WEEK.—This mine, above Michigan Bluff, has opened on a richer strata of gravel than ever—that hardly seems possible, unless it is all gold.

SISKIYOU COUNTY.

DISCOVERY OF QUARTZ LEDGE.—Yreka Union, March 29: We understand a new quartz ledge has been discovered recently on Eddy Gulch some 3 miles from Sawyer's Bar. The ledge, it is reported, is 3½ ft. thick, has been traced for some distance on the surface by the cropping, and is marvelously rich.

TUOLUMNE COUNTY.

OLD TUOLUMNE CLAIM.—Sonoma Independent, March 29: This Quartz Co., three miles north of Columbia,

above Summit Pass, have struck richer rock than ever. They have been running a tunnel to tap and drain the mine at a depth of 60 ft., and the prospect is that they will be liberally rewarded for their enterprise, by developing one of the best quartz veins in the county.

OLD CAMPBELL LODE.—This lode is situated on the American Camp road, below Morgan's mill, about 3 miles above Columbia. On Saturday we saw a prospect of \$1.50 from 3 pans of the casing. The vein is a good one, as is proved by rock that has been tested at a distant mill, and found to net from \$15 to \$20 per ton. Rock is easy to get out, and the prospect is that they will work six years ago, and over \$7,000 taken out, but being unable to procure the necessary machinery to work to advantage, like many miners in similar circumstances, they gave up a good mine and scattered.

Nevada.

ELY DISTRICT.

SILVER PEAK.—Pioche Record, March 23: Considerable ore, considering the means of hoisting, has come up during the week through the main shaft. Ore bodies are being exposed. The following are the results of assays made since our last: Mine sample, \$33.60, on the 19th; do, \$175.20, on the 20; do, \$55.50 and \$50.20 on the 21st and \$45.04 yes erday. The width of the ore vein is now about 12 inches.

PIOCHE-PROXIMA.—Some little embarrassment has been encountered from the scarcity of timber for the main shaft. The rock is now much softer than it has been since commencing the shaft, and it is believed the contractors will be able to make 8 ft. in 24 hours. A number of feeders of the main ledge have been cut the last 10 ft., some of which assay high. A good ore body must be near. Developments in the old works continue satisfactory.

WYANDOTT & CHASE.—About two tons of ore a day being hoisted, and about 175 tons on the dump. The assays vary, but there is no doubt that the mill yield will not fall short of \$100 to the ton. The rock has become softer, and much better progress than usual is being made in the shaft and drifts.

MEADOW VALLEY.—We know but little about this mine, save from hearsay, but "common report" among local miners says it is to be the "biggest" this year in the State—or rather, that millions are "in sight," which will be hoisted some time this summer.

RAYMOND & ELY.—Not less than 900 tons of ore have been delivered at the mills during the week, two-thirds of which is first-class. From 115 to 120 tons a day are being hoisted. The ore breasts never looked so good in all the history of the mine. The slopes are all being worked to the fullest extent.

PROCTOR.—Ore has been reduced at the Magnet mill during the week, but the returns have not been all received. There are still 150 tons of good ore on the dump, which, judging from the yield so far, ought to pulp over \$150 to the ton. Unaltered quantities continue to be hoisted, and the mine continues unchanged. Full force engaged.

EXTERMINATE.—From 10 to 15 tons of high grade ore are being shipped daily to the Magnet mills. Large quantities of ore continue to be brought to the surface. The main shaft is down 280 ft. Ore bodies large.

ALPS.—The drift from the 160-ft. level has cut a 4-ft. vein of very rich ore, some of the assays running up to \$200 to the ton. The ledge dips to the south. The ore breasts in all parts of the mine are looking well. The drift at the 300-ft. level is in 34 ft.

MONTANA.—This mine is looking better now than ever before. Few mines in the district expose a better defined or larger vein.

PEAVINE.—The ledge is widening out at two points, the ore containing its average richness. Still drifting on the ledge, the vein continues to yield high-grade ore throughout an extent of 150 ft. There are large bodies exposed.

STAR OF THE UNION.—The vein under which the incline runs was tapped 210 ft. from the surface, and a quantity of the ore was extracted for testing. It looks very rich.

EUKEKA.—First-class ore was worked at the Magnet mills during the week, the pulp assay averaging \$224.60; second-class rock, \$125.40.

LOUISIE.—Work is now confined to the 200-ft. level. Two fine seams of ore have been cut during the week. The drift for the last 15 feet has been through mineral-stained ledge matter.

EUKEKA.—The shipments for the week have been immense, notwithstanding only \$50,525, have been returned from the express office. We are well assured much more has been carried out by other means.

STAR DISTRICT.—The reports from Star District, 90 miles northeast of here, in Beaver County, Utah, continue very encouraging. The principal developments are on the Hickory ledge, sold a short time ago to the Star Co. An incline has been sunk on the ledge 130 ft. and it is claimed 600 tons of ore have been extracted in sinking the incline that distance. It is free milling ore, and is said to average \$250 to the ton. Machinery is now on the road from Salt Lake for hoisting works and a 20-stamp mill. Other rich ledges are also being developed.

EUKEKA DISTRICT.—This is 6 miles from the Meadow Valley, and about 30 miles south of Bullionville. The Clingmuth ledge is leading in development. The shaft on it is now down 114 ft., and 2 ft. of good ore is exposed at the bottom. It is of the free milling class, and assays from \$30 to \$300 to the ton.

EUKEKA.

PAUL JONES.—Eureka Sentinel, March 25: We made an error in the figures of the assayer's return upon one of our mine, in our local item of Saturday. The highest assay given should have been \$2,800, instead of \$2,400 per ton. Several assays resulted in a return of \$2,300, \$2,400 and \$2,700 to the ton. There are upwards of 30 tons on the dumps, beside a large quantity sacked up for shipment.

CHAMPION DIAMOND DISTRICT.—We saw some fine ore from the Champion last evening, assays from which gave a result of \$312 per ton in silver. There are several mines in the vicinity of equally good quality in ore. These are, Champion South Extension, Bamboo, and Graet.

AN IMMENSE MINE.—Eureka Sentinel, March 26: We learn that the body of ore recently struck in the old Richmond works is, day after day, as explorations are extended, assuming larger proportions. It is some distance up the hill from, and south of the Tip Top incline, though not within the limits of the territory now in dispute between the Richmond and Eureka Consolidated. It has been said that in the event of the Richmond company losing the pending suit, the London Directors would probably decide on abandoning this district, but as it now appears there is an abundance of good ore in the mine, free of all dispute, the idea, if ever seriously entertained, will likely be discarded. The company deserves to be protected in its investment, but we submit that much trouble might have been averted had a careful, practical management, been the order of things. The amount of high grade ore in the Canon, and in that part of the mine under dispute is said to be perfectly astonishing—one surveyor putting it at a million of tons, and other good judges at even higher figures.

THE KENTUCKY MINE.—Eureka Sentinel, March 30: The Eureka Mining Co. has two shifts at work on the tunnel which is being run to strike the ledge. The intention is to carry the tunnel 450 ft. in the hill, at which point it ought to cut the lode at a depth of 240 ft. Large quantities of high grade melting ore were taken from this mine two years ago and there is good reason to believe that ere long it will be more productive than ever.

RICH ORE.—J. B. Osborne returned yesterday from an inspection of the Golden & Bender mine in Sevier Canon, and brought a very fine piece of horn silver ore with him. It appears that the main shaft is down 140 ft. and drifts are being extended from the bottom of it.

(Continued on Page 220.)

The Mendha Company's Mines.

The Mendha Mining Company, at Higbland, own two ledges, which they are energetically developing, and from which they have taken out, ready for crushing, from 1,000 to 1,200 tons of ore. Their fine new mill will be in operation before long, when reduction will begin and continue night and day. If expectations are realized, Higbland will develop into one of the richest silver-producing districts in the State, and we have confidence in the success of the Mendha Company's enterprise. The first ledge in order of consideration is

The Mendha Mine.

It is about a mile and three-quarters west of the Mendha mill, the principal developments being in and on the east rim of a well-wooded cañon, which the ledge crosses from east to west. The mine is 7,600 feet above the sea level, and 200 above the mill-site. Just below the development the cañon opens out into a beautiful grassy glen, with overhanging cliffs, covered with cedar and dwarf pine. The country rock, through which the ledge trends as far as opened, is a close-grained gray limestone. The ledge runs almost directly east and west, and can be traced by the croppings for hundreds of feet. A tunnel has been started on the west side and at the bottom of the cañon, and follows the ledge in to the westward a distance of three hundred feet. It is four and a half feet wide and six high. Work continues in it, and it will be driven in four hundred feet further, at least, before suspending operations. The dip of the vein is from the south to the north, the incline being about seventy-eight degrees. The vein varies in width from the mouth of the tunnel to the face, from six inches to five feet, but its average extent may safely be set down at two feet, as it is strong and well defined the greater distance. At a point 200 feet from the mouth of the tunnel it widens out to six feet, the ore being very rich, assays running from \$80 to \$400 to the ton. This, too, is about the range of cropping assays, the ledge being as well defined for 700 feet on the surface as in the tunnel. The tunnel at its face is 170 feet below the surface, but the ledge crops out on the surface 700 feet west of that point. The ore is of the sulphuret class, carrying large percentages of lead and iron. Professor Mathey feels great confidence in his ability to reduce them and save all the silver, says he has had considerable experience in the reduction of similar ores. The vein walls are of the same general formation as that entire district—close-grained grey limestone. Between the vein matter and walls there is a thin layer of pure white lime, which leaves its mark on what it touches, like chalk.

The main shaft of the Mendha mine is 306 feet east of the tunnel. It is now down 210 feet. The ledge at that point goes down straight a great distance, the shaft following it the first 100 feet. It then dips to the north. Where the shaft leaves the vein, 100 feet down, the mineral body is 13 feet wide, but the ore is low grade, the average assay being \$73. The average width of the vein to the first level is set down at three feet, much of the ore being high grade, assays running as high as \$400 to the ton.

At least 600 tons of ore have been taken out of the tunnel and main shaft of the Mendha mine, and only "dead" work, so far has been done.

Excellent steam-hoisting works are in operation, with blacksmith shop connected. Attached to the engine is a first-class condenser, and the mine is aired by the patent, noiseless fan-wheeled ventilator.

The contiguous hills are covered with growing timber, admirably adapted to all mining purposes.

The Mendha mine was discovered by a party of prospectors in the fall of 1869. They got the name from the Indian heroine of one of Ned Buntline's famous border fictions.

The Arizona Mine

Is also owned by the Mendha company. It is reached by ascending the mountain to the east of the Mendha mine to its summit. At the discovery shaft it is 8,400 feet above the sea level. The formation it is in is the same as that of the Mendha, and the ore looks as much like the Mendha ore as one pea like another; but, strange as it may seem, the vein, at discovery, is as flat as a floor, and trends north and south, while the Mendha's trend is east and west. The vein, in some places, is 18 feet wide, and in no place developed has it fallen below 3 feet. Six hundred tons of the ore are out, and 6,000 at least, are in sight. Some of it assays as high as \$450 to the ton, and it has never fallen below \$70. Of course this cannot be a regular vein; but about 100 yards below this immense mass of ore the regular ledge was discovered, running in the same direction, with about the same dip, and between exactly the same walls, as the Mendha, a mile to the west. No doubt they are one and the same ledge. Professor Mathey himself discovered the regular vein of the Arizona. The vast flat deposits of ore above—the origin of which we cannot and will not attempt to account for—were discovered by some prospectors from Arizona in the fall of 1869.

A 1000-foot tramway is being constructed from the Arizona mine toward the main road to the mill, by means of which the ore can be delivered for reduction very cheaply.

The Arizona, like the Mendha, is surrounded by an abundance of fine growing timber, adapted to every use in the mine's development. But there is no natural water supply at either

mine. This, however, will be no drawback, as the returning ore vehicles can furnish an abundance of water.

The developments of the mines of the Mendha Company is under the immediate supervision of Mr. Hugh Mullen, a practical miner of great experience.

We believe Professor Mathey will soon demonstrate that Higbland is one of the best silver camps of the State. The mines are among the most promising we ever visited.—*Pioche Record*.

Montana Ore Shipments.

From what we learn from the mining districts there will be a large amount of ores shipped to foreign points this season for reduction. The transportation has been all or nearly to Montana and none or nearly from Montana, notwithstanding there are thousands of tons of high-grade ores on the dumps, and the owners have held them as dead property and paid more interest on money to develop their mines than the transportation of their ores to foreign reduction works would cost. Freighters can take back half-loads to the river and railroads, at about the same cost as they can go empty, and will make freights reasonable to acquire the freight. From Bannack we learn rates can be readily secured to Corinne at \$20 to \$25 per ton; from Butte, Vipond, and that vicinity, \$30; from Philipsburg, probably \$35 to \$40. These figures will cover the freight from any quartz camp in Montana to Corinne. Central Pacific rates from Corinne to San Francisco do not exceed \$20 per ton. There they can be sold at fire assay values, or reduced at reasonable terms. With the immensity of high-grade ores out that will pay a large return over these costs of transportation and reduction, there is no good cause why the owners should not select and ship at least such quantities as will enable them to prosecute the development of their leads without "soaking" their mine for the "where-withal" to do it. It may be a long time before reduction can be so perfected here that the results will be as satisfactory as those obtained abroad, and even were railroads built the net cost of laying ores down in San Francisco would not be materially lessened from many of the camps. There should not a wagon go empty to Corinne this year. There are thousands of dollars lying at the mouths of the shafts and tunnels of Montana quartz lodes in ores that will pay good margin on shipment—better, perhaps, than you will get out of them for years here. Combine together if not able to act individually, make arrangements with freight agents and responsible parties in San Francisco, or wherever you ship to select and pack your ores and start them the first opportunity, and if your ores have value you will get such returns that you will not need to "see your Uncle," but will have money to develop your leads.—*New Northwest*.

Pacific Coast Appropriations by Congress.

The following is a summary of special items for California, contained in the various general appropriation bills passed by the last Congress: Indian bill, \$940,900; for legislative purposes, etc., \$338,705; for fortifications, \$240,000; for Post Offices, \$950,000; for river and harbor improvements, \$100,000; naval purposes, \$98,809.75; Sundry civil appropriations, \$1,839,549.80; deficiency, \$218,287. Total for California, \$3,724,147.42. This sum is equal to more than four times the aggregate for all the remaining Pacific Coast States and Territories.

The aggregated items of Nevada are as follows: Indian Bills, \$27,500; Legislative purposes, \$144,400; Sundry Civil purposes, \$53,700; Deficiency, \$52,975.53. Total for Nevada, \$293,573.88.

The aggregated items for Oregon are as follows: Indian Bill, \$153,850; Legislative purposes, \$795; River and Harbor Improvements, \$23,000; Sundry Civil appropriations, \$178,500; Deficiency, \$960.58. Total for Oregon, \$363,310.58.

The aggregate items for Arizona are as follows: Indian Bill, \$341,000; Legislative purposes, \$26,500; Sundry Civil Appropriations, \$72,811.80; Deficiency, \$152,523.77. Total for Arizona, \$593,835.58.

Aggregate items for Washington Territory are as follows: Indian Bills, \$11,185; Legislative purposes, \$44,509; Sundry Civil Appropriations, \$11,585; Deficiency, \$1,783.22. Total for Washington Territory, \$73,983.22.

It is possible that some of these items, especially those pertaining to surveys of the Pacific Coast, and collection of mining statistics, etc., contained in the aggregate amounts for California, may be partly used for Nevada, Oregon and Washington Territory.

COAL IN INDIA.—A small quantity of coal obtained from the pits recently sunk at Sasti, near Chandah, in his Highness the Nizam's Territory, has been experimented upon by the Peninsular and Oriental Company's agent at Bombay with a result that has far exceeded the most sanguine expectations. The agent, we believe, has reported that on comparing the Sasti with Newcastle coal, the consumption of the former for a given period only exceeds that of the latter by 22 per cent. in quantity; and when it is considered that the specimen experimented upon was by no means the best obtainable from the Sasti pits, and that it had for some months previous been exposed to wind and weather without any protection, the result is a highly satisfactory one. The exploring party at Warungal have come upon an excellent seam of coal at a place called Singareddy.

Cherry Culture.

Among the early fruits of the season none are more acceptable than the cherry. As with strawberries, so with good ripe cherries, almost everybody likes them; but to grow them everywhere successfully in California is a very difficult matter. We are going to show, however, that very much depends upon skill or mode of culture. Where we find a man who has made the culture of any variety of fruit a specialty, giving his chief attention to a particular kind of fruit, experimenting for years, in a climate like ours, we are prone to believe he has learned something that everyone don't know.

With this view of the subject, we introduce to our readers the practice of Mr. Wm. C. Geiger, at his place, two and a half miles west of San José. This gentleman has made the growing of fine cherries a specialty, and has been eminently successful, and yet, the first question a person would be likely to ask on seeing his cherry trees, would be—Why don't he trim up

Fig 1.

Fig. 2.

TRAINING THE CHERRY TREE.

his trees, and make them look like something?

All who have attempted to grow cherries in California, know how prone the trees are to make an enormous upright growth, almost destitute of side limbs, and generally producing a tree of which Fig. 1 is a type. It is common to give to cherry trees in this climate a low trunk, better to shade it from the effect of the sun's heat, but still it is common to trim to a smooth trunk from two to four feet from the ground.

The method so successfully pursued by Mr. G. is quite the reverse of this, as indicated in Fig. 2. To commence with his mode of culture, we begin with his seedling trees which he procures at one year old from Eastern nurseries, from six to eight inches in height. These are set out, headed back and make a growth sufficient for hudding in July or August a few inches from the ground. These trees at one year old from the bud, and two from the seed, are then set out where they are to stand, and now comes in the first of the peculiar treatment they are to receive.

Every bud upon the entire length of the body is allowed to grow and produce a shoot, and when these shoots or limbs—all but the upper terminal one—have attained a length of six or eight inches, they are checked by pinching out the terminal bud; the effect is to convert them into fruit spurs. This practice is continued up to the point where it is desired to have the tree form its top; which in Mr. G.'s practice has been from 2½ to 3 feet from the ground, though in future he will adopt 2 feet as the rule.

At this height the side shoots may be even a foot in length, but by being frequently pinched in, are almost entirely fruit-bearing spurs. In forming the head of the tree, a similar practice is adopted, except that now as in Fig. 2. the side shoots are allowed their full length, but the one central shoot which should always be maintained in cherry trees, is checked in its upright growth when 18 inches long, by pinching the terminal bud. This has a tendency not only to cause a spreading habit in the tree, but

it also causes a thorough ripening and full maturity of the wood.

The next year and the next, the same course is pursued, at any and all times pinching in the terminal buds when they have reached a length necessary for the perfect symmetry of the tree, as in Fig. 2. The rationale of this method is this, the side shoots along the trunk of the tree to its first regular limbs, serve to shade the bark from the intense heat of the sun, so that there is never a "sunn scald" of the bark so injurious to all trees, both from direct cause and from the borer which always attacks the tree if at all, in these dried sun scalds.

Another excellent effect produced by the growth of these side limbs, is the strengthening of the trunk of the tree, giving it enlarged size and vigor, every leaf adding its quota to the direct growth of wood. As an offset to what may, by some be deemed an unsightly object because of the growth of these trunk limbs, we offer this, that as many as three pounds of asplendid cherries as the tree can grow, are produced upon these fruit spurs below the regular limbs or branches forming the head of the tree.

As regards the simple matter of form, we cannot even see that Fig. 1 with its smooth-trimmed, naked trunk, has a particle more of beauty about it than Fig. 2, although it has always been the fashionable cut and trim for orchard trees. When the top of the tree becomes large, these side shoots from being much shaded, naturally drop off, but leaving no large scars or wounds as where the knife is injudiciously used. Mr. G. never uses the knife in giving form to his young trees, but relies entirely upon his fingers and the pinching-in process.

We had intended to speak further of Mr. G.'s success in cherry culture, number of trees, best variety for general culture, home market and shipment; mode of culture pertaining to the soil, etc., but which, owing to the length of our article already, we must defer.

A Wonderful Well at Pioche.

For eleven months, says the *Pioche Record*, Mr. Frank Takats and Charles Netzel have been engaged sinking a well on the flat north of the city. They are now down 322 feet. For 300 feet the shaft went through a compact cement or conglomerate rock formed of limestone and quartzite; at that depth a stratum of wet varicolored clay was encountered, soft and pliable enough to be rolled into marbles in the palm of one's hand; this clay streak, or layer, was passed by sinking two and a half feet further, when a sand concrete was encountered, very solid and compact; and the shaft continued to be sunk through this formation a foot or two, when the workmen were surprised to hear strange gurgling noises from below, as of splashing water, accompanied by occasional rumbling sounds, such as is made by rocks colliding with each other in a turbulent, rapidly flowing torrent. Finally, a little fissure, or crack, about half an inch in width, was discovered running across the bottom of the shaft, which was characterized by an air draft of great force, all the small fragments falling near it being sucked in. From this crevice in the close sandstone formation issued the strange sounds. A lighted candle held close to it was instantaneously extinguished by the draught. The workmen continued sinking a few feet further, when the evidences were too strong of a vast chamber below coursing through by a subterranean current of great body, to be longer doubted, and work was temporarily suspended. In the meantime, the hoisting of gravel, with the means at hand, had become too slow and laborious for much progress to be made.

Messrs. Takats & Netzel, now that they have sufficiently demonstrated that an abundance of water is obtainable by sinking, solicit assistance from citizens in erecting a whim, and continue their developments until water is reached and the necessary machinery put in place to bring it to the surface in inexhaustible quantities. They will certainly receive all the assistance they need, for where water sells at from three to four cents a gallon, as it does in Pioche, an unfailing well must be considered the best of property. As the air from the draught of the fissure is fresh and pure, it is almost certain that the water below is likewise fresh and pure. Now, why should we not expect to find a subterranean river in this locality? No running streams exist within miles, and no springs, to speak of. Our water is furnished from a few fountains several hundred feet above the city level, and surrounding us are high mountains, on some of the summits of which snow lies the greater part of the year. If the hope should be realized, it is very probable that the desert to the north of us will soon be transformed into fields of fertility, for the soil is naturally rich, and water is only necessary to make it highly productive.

Useful Information.

Spoiling Mirrors.

It is a fact worth knowing, but which does not seem generally understood, that the amalgam of tin foil with mercury which is spread on glass plates to make looking-glasses, is very readily crystallized by actinic solar rays. A mirror hung where the sun can shine on it is usually spoiled; it takes a granulated appearance familiar to housekeepers, though they may not be acquainted with its cause. In such a state the article is nearly worthless; the continuity of its surface is destroyed, and it will not reflect outlines with any approach to precision. Care should therefore be exercised in hanging. If any of our readers have mirrors which appear to be spoiling, it would be well to ascertain whether the direct sunlight strikes them. If thus exposed, they can probably be saved from further injury by simply changing their position. The back as well as the front must be protected. A small glass hung in a window, where the rays strike it behind, is peculiarly exposed. The back should always be covered where the beams are likely to touch it.

The greatest danger to looking-glasses, however, is in transporting them. Very expensive ones have been seriously injured by careless handling when merely carried across a street. The men who move furniture are seldom fully aware of these possibilities, and need to be cautioned and watched. Frequently a man or boy may be seen in the street carrying a mirror in such a way that the full glare of a noon-day strikes and injures it. Owners of such articles would, as a rule, be able to keep and use them much longer if they would exercise much caution in this regard. To re-silver a pier-glass often costs as much as one-fifth of the original price of the article; while the common glass is seldom worth re-silvering.

It is also well to avoid hanging a mirror near a stove or fire-place, where the heat radiated can reach it. If this precaution is neglected, granulation is likely to occur, even in a comparatively dark room, by the influence of warmth instead of light. A lamp or gas jet, if placed too close while burning, though it may not crack the glass, will also often bring about the same injurious crystallization, and will even sometimes cause the amalgam to melt and run off.—*N. Y. Mercantile Journal.*

Pewter.

The principal constituents of pewter are lead and tin; the proportions of the two metals depending somewhat on the use to which the alloy is put. The best contains but sixteen to twenty per cent. of lead. Of this plates and dishes are made, which look like block tin, and can be brightly polished by rubbing. The addition of more lead cheapens the commodity, and gives it a dull bluish appearance. In France pewter vessels for wine and vinegar contain eighteen per cent. of lead. It has been found that a large portion of that metal in utensils for this purpose is liable to result in the formation, in the liquid, of the poisonous acetate or angar of lead.

A little copper added in making pewter hardens the compound and renders it sonorous, so that toy trumpets and other rude musical instruments can be made of it. If the copper is replaced by antimony, hardness and a silvery luster are the result. If the contents of the melting pot are stirred with a strip half of zinc and half of tin, or if a lump of zinc is allowed to float on the melted metal during the casting, the vaporized spelter seems to protect the fluid mass from oxidation, and prevents the formation of dross. Hence it is said to "cleanse" the mass.

Jewelers use polish and laps of pewter, and sheets of the article are to some extent used for cheap engraving, music notes, or other figures being stamped on it instead of being cut with a burin or graver. The ease with which it melts enables it to be employed by tinsmiths and tinkers for solder. Care must be taken not to set pewter dishes, mugs, spoons, lamps, etc., on stoves or other hot bodies, as, if left for any time, they are liable to settle into shapeless lumps.

IMITATION OF MARBLE.—Imitations of marble are in great demand for ornamentation, and many different compounds are used for the purpose. Mr. Pichler, a glider in Vienna, from his own experience, recommends the following composition as being simple and satisfactory: Into one pound of best joiners' glue, boiled rather thick, half a pound of rosin (colophonium) is to be slowly stirred. (Instead of the rosin the same quantity of Venetian turpentine may be used.) Into this plastic mass is worked a mixture of powdered chalk and of any mineral color of the desired shade, and after the addition of a little olive oil it is ready for moulding. It is sometimes convenient to have the material in the shape of thin sheets to be cut as required; and in this case the mass is rolled out upon a slightly heated plate. Mr. Pichler asserts that this composition hardens rapidly, and can be easily polished. When kept for a length of time it should be wrapped in a moist sheet, and exposed to gentle heat before using. The variegated marble-like veins can also be produced by kneading together differently colored portions of this mass.

ALCOHOL IN FOOD.—The alcohol is not destroyed, but evaporated by the heat of cooking the food. In the preparation of extracts, the heat is intentionally not raised high enough to drive all the alcohol out by evaporation, as some alcohol must be retained, in order to prevent the extract spoiling. So the alcohol in wines serves two purposes, firstly, to prevent this spoiling (wines deficient in alcohol do not keep); and secondly, as a solvent for the ethers peculiar to the different wines. The alcohol is present in pure wines in so small quantity that no moderate use at table can intoxicate.

GOOD HEALTH.

[From our New York Correspondent.]

The Fallibility of Medico-Legal Jurisprudence.

One's confidence in the testimony of "experts" is apt to be a little shaken by such absurd and contradictory evidence as we have been favored with in the Schœppe and Wharton trials. If these were exceptional cases, we could put them aside and soon recover our faith. But they are only instances of what is happening every day. Acknowledged scientific men, with remarkable uniformity, flatly deny each other's assertions from the witness-stand. "The learned gentlemen's solutions were imperfect, his filtrates impure, his precipitates ambiguous. Just listen to me for a moment and I will convince you of the dazzling whiteness of black." This sort of thing is entirely too common. With all respect to the profession, why is it, we ask, that you fail to distinguish between human and other blood corpuscles (as in the late Boston trial); or between the orange sulphide of antimony and the innocuous canned tomato? Even in so simple a matter as the detection of arsenic, errors are frequent.

A family in the vicinity of New York were all taken sick at once and manifested symptoms of arsenical poisoning, the doctors said. It was the brilliant new carpet that did it, of course. So an expert was called upon to examine the accused carpet for arsenical dyes. Needless to say, he found an amount proportionate to his fee. So a suit was brought against the seller of the carpet for damages, he, to cover himself, began another action against the wholesale dealer who sold it to him; the wholesale man passed it back upon the manufacturer; and the manufacturer upon the party who sold him the dye-stuff. There was no end of chemical evidence. Experts were more numerous than the trials. Finally it occurred to the dyer, who was in a bad way, having no one back of him to prosecute, to have a fresh analysis made of this much abused carpet by Dr. Chandler who pricked the legal bubbles by satisfactorily proving that there was not a trace of arsenic present!

It is easy enough to criticize. But how, or where, or when, can we look for a remedy? Charlatans are in the "expert" line, as well as every other. Who is to decide as to the capability of an analyst? A scientific school diploma doesn't seem to be as reliable an endorsement as that most respectable document is usually considered. Nor does previous success always guarantee future precision, as we find to our cost.

The truth is that the whole question of chemical analysis in the matter of poisons is not at all on a par with the rigidly accurate results of the bullion assay, for instance. Intelligent juries are rather slower in convicting on such testimony than of old. And the more thoroughly scientific a chemist is, the more readily will he acknowledge his weakness. It is only the quacks who will swear positively to their tests in doubtful cases. Most of our best American chemists refuse to touch the poison business. There are exceptions—as Dr. Chandler and Dr. Doremus, who are undoubtedly at the head of the profession. Such men can not suffer from contact with the ordinary run of "experts," and may venture where the average chemist would be contaminated.

A. W., JR.

THE EFFECT OF DIFFERENT COLORED LIGHT UPON RESPIRATION.—The animal to be experimented upon was placed in an airtight box into which no light could penetrate except such as passed through glass of a given color. Air freed of carbonic acid was constantly admitted into the box, and escaped by a second opening, where it was passed through a vessel which contained some absorbent of carbonic acid, so that its amount could be accurately determined. Representing the quantity of carbonic acid respired by a dog in a given time, under white glass, by 100, the amount given off under black glass was 82.7; under violet, 87.78; under red, 92; under blue, 103.77; under green, 106.03; and under yellow, 126.83. The difference was still greater when the experiment was tried on a pigeon and on a hen. The authors came to the conclusion that green and yellow rays, which are the most important to the vegetable kingdom in taking up carbonic acid, are also most favorable to the respiration of animals—that is, enable them to give off the most carbonic acid.

EATING LATE.—It is very injurious to eat just before retiring. The desire for it is simply the result of habit or of a morbid craving—and should be at once overcome.

MISCELLANEOUS.

How to Dish up Oatmeal.

OATMEAL PORRIDGE.—Take six table spoonfuls of meal and soak it over night in a pint and a half of water; in the morning stir it up well, and place the pail into a kettle of boiling water; let it boil for half an hour, as hard as possible; then stir in a cup full of milk and let it boil fifteen minutes. Season with salt, and eat with cream and sugar. Soaked over night, it requires much less cooking. A large supply can be made in cold weather, for it warms over as good as when fresh. It can also be made without the addition of milk.

UNFERMENTED OAT CAKE.—Soak one pint of meal in one pint of buttermilk, over night; next morning add one small tea-spoonful of saleratus, dissolved in water, and wheat flour enough to roll out into thin cakes; bake on flat tins in a hot oven.

OATMEAL AND COCONUT CRACKNELS.—Oatmeal mixed with grated cocoanut produces a very attractive cake to both old and young. Take three heaping table-spoonfuls of grated cocoanut, or two of this prepared "dessicated" cocoanut; add to it half a pint of the finest oatmeal, and two heaping table-spoonfuls of sugar; stir it into one gill of boiling water, and mix it thoroughly together; turn out on the rolling board, well-floured, and roll it as thin and cut out as for common cracknels put a bit of citron and half a dozen currants into each cake, sticking them into the dough. Bake in a slow oven, and watch carefully, lest they brown a shade too deep. To make them crispy let them stand a day in an uncovered dish. A very palatable pie crust can be made from the dough of oatmeal cracknels by wetting it a little thinner; or in preparing it, add just half the measure of meal in hot water. Add no butter or lard, simply a little salt; roll out thin, and make the pie of cooked fruits, as this kind of paste bakes very quickly, and if the fruit requires cooking, it would become too hard and brown. Most persons who eschew all kinds of pies can eat those made of oatmeal without fear or trembling, and they will soon learn to consider oat meal an invaluable addition to their tables.

OATMEAL BREAKFAST CAKE.—Take one pint of oatmeal, a pinch of salt, and just warm water enough to stir it up into a batter, like griddle cakes. Pour it into a shallow baking pan, and bake it for twenty minutes in a hot oven. But if on a cold morning your oven refuses to heat, turn your batter into a greased "spider," or frying pan; set it on the top of the stove and cover it closely; bake it fifteen minutes. Break open the cakespread with butter, you will find it quite toothsome. Or, if you prefer, bake it in small cakes on the griddle iron, first putting in a handful of wheat flour and a little more water. The cold porridge will also make delicious griddle cakes.

OATMEAL CRACKNELS, OR SCOTCH BANNOKS.—Take the finest quality of oatmeal stir in barley and enough water to wet it through, add a pinch of salt; let it stand ten minutes to swell; then roll it out a quarter of an inch in thickness, first flouring the board and rolling-pin with flour, cut it with a biscuit cutter, and bake in a moderate oven, as these cakes will burn quickly, and only require to be of the lightest brown. They will snap easily between the fingers, and are delicious for lunch and when prepared and baked just right, they have a pleasant nutty flavor that is very agreeable, and requires no butter to make them palatable. Put into a close jar, they will keep several months. In the Highlands they preserve their bannocks in the barrels of oatmeal, and keep them a year or so.

A COMMON ILLUSION.—There are few greater illusions, than that which attributes the results of too much eating and drinking to excessive mental labor; and it is one of those fictions the author of which invariably comes to believe himself. We have among us hosts of hypochondriacs who are always calculating the effect of work on their system, and who base their calculations on headaches, and fits of nervous prostration, and symptoms of lassitude that have no more to do with intellectual exertion than they have to do with the Gulf Stream. They are, for the most part, the natural result of too many invitations to dinner, of incautious and intemperate consumption of food and drink at unseasonable hours, and of a curtailment of sleep occasioned by getting home early in the morning.

Sewing Machines.

Few, we think, are aware of the immense number of sewing machines which is required to meet the annual demand for this now indispensable adjunct of the household. The *Hartford Times* has given the actual returns of the State of the different manufacturing companies for a single year—1872, and doubtless the number is but very little in excess of any previous year during the last decade.—We copy as follows:

	Machines
The Singer Manufacturing Co.....	312,758
Wheeler & Wilson Manufacturing Co.....	174,083
Howe Machine Co. (estimated).....	154,000
Grover & Baker Machine Co.....	52,010
Domestic Sewing Machine Co.....	49,554
Weed Sewing Machine Co.....	42,444
Wilcox & Gibbs Sewing Machine Co.....	33,639
Wilson Sewing Machine Co.....	22,663
American B. H. O. Company.....	18,930
Gold Medal Sewing Machine Co.....	18,897
Florence Sewing Machine Co.....	15,797
B. P. Howe Sewing Machine Co.....	14,907
Victor Sewing Machine Co.....	11,901
Davis Sewing Machine Co.....	11,376
Bless Sewing Machine Co.....	6,663
Remington Empire Sewing Machine Co.....	4,983
J. E. Breunsdorff & Co.....	4,262
Keystone Sewing Machine Co.....	2,665
Bartlett Reversible Sewing Machine Co.....	1,000
Bartram & Fenton Manufacturing Co.....	1,000
Secor Sewing Machine Co.....	811

Total for 1872.....851,736

These remarkable facts show how literally, how generally, the new sewing machine has become a household necessity. By far the greater number of these machines were sold at enormous profit. Owing to a combination on the part of a few leading machines, all the latter inventions have been obliged to agree to sell at the rate not less than \$60; otherwise not even the payment of the royalty demanded in every such case could avail to give them the right to use the peculiar patented "feed" movement on which the success of every sewing machine is supposed to depend, and of which three or four have a monopoly. Thus a machine of which the total cost, for making, is not more than \$15 or \$18, sells for \$50, \$70, or \$80, according to the style and finish. The larger part of these sales are to sewing women who have to work for a living, and to families of moderate means. There should be no good reason why machines as good as Singer's or Wheeler & Wilson's could not be sold for \$30 apiece.

CHAPPED HANDS.—In a healthy condition the skin is kept supple by an oily secretion, which answers the same purpose as oiling leather. During warm weather this secretion, in common with all the other secretions of the skin, is more abundant than in cold. When it is insufficient the skin becomes dry and harsh; and in those parts of the body where the skin is thick and subject to much motion, as on the hands, it readily cracks or fissures. The amount of this secretion is so much reduced in cold weather that the frequent washing of the hands with soap causes them to chap readily, and this the more certainly if the soap is not thoroughly washed off. The alkali in soap is usually in excess, and this combines with the oily secretion, and so deprives the skin of its natural lubricator. To prevent the hands from chapping, then, be careful to wash all soap from them thoroughly in clean water. This will ordinarily suffice; but if not, it will be necessary to make good the removed oil by the use of glycerine, honey, mutton tallow, etc.

BETTER THAN GOLD.—We often hear little boys telling of the wonders they will do when they grow to be men. They are looking and longing for the time when they shall be large enough to carry a cane and wear a tall hat; but let me tell you, little boys, what is a great deal better than money, and what you may be earning all the time you are waiting to grow large to earn a fortune. The Bible tells us that a "good name is rather to be chosen than riches, and loving favor rather than silver or gold." A good name does not mean a name for being the richest man in town, or for owning the largest house. A good name is a name for doing good deeds; a name for wearing a pleasant face, and carrying a cheerful heart; for always doing right, no matter what we may be.

IT IS A CURIOUS FACT.—Illustrating the necessity of cleanliness and of keeping the pores of the skin open, that if a coat of varnish or other substance impervious to moisture be applied to the exterior of the body, death will ensue in about six hours. The experiment was once tried on a child in Florence. On occasion of Pope Leo the Tenth's accession to the Papal chair, it was desired to have a living figure represent the Golden Age, and so a child was gilded all over with varnish and gold leaf. The child died in a few hours. If the fur of a rabbit or the skin of a pig be covered with a solution of india-rubber in naphtha, the animal ceases to breathe in a few hours.

GENERAL EDITORIALS.—Work on Mining Claims to Prevent Forfeiture, 209. The Emma Mine Troubles; Railroad Management, 216.

ILLUSTRATIONS.—Prait's Steam Pump, 209. Cherry Tree Training, 214. Emerson's Patent Stone Saw, 217.

SCIENTIFIC PROGRESS.—Curious Effect of Light on Selenium; Remarkable Telegraphic Feet; Uncontrollable Fire; The Northern Lights Referred to Electricity; Oxidation of Alcohol; Necessity of Rest for Plants; Minuteness of Spectroscopic Research; Heat and Density; New Method of Cleansing Glasses; Researches on the Alcoholic Fermentation; Absorption by Phosphorus; Bleaching by Turpentine; The Million Dollar Telescope; Improvement in the Manufacture of Glucose, 211.

MECHANICAL PROGRESS.—Tempering Steel; Tungsten Steel; New Method of Plating; New Preparation of Paper as a Building Material; A Lesson in Friction; Micro Head Light for Locomotives; Mechanical Wood Carving; Coke from Lignite; Hardening Burned Steel; Complaint to American Mechanic; A New Plating Process, 211.

USEFUL INFORMATION.—Spilling Mirrors; Pewter; Imitation of Marble; Alcohol in Food, 215.

GOOD HEALTH.—The Fallibility of Medical-Legal Jurisprudence; The Effect of Different Colored Light Upon Respiration, 215.

MINING SUMMARY from various counties in California, Nevada, Idaho and Montana, 212-13.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 211.

MISCELLANEOUS.—Utah Smelting Furnaces; Discovery of Relics of an Ancient Civilization; Mineral Resources of Costa Rica; Montana Mining Prospects for 1873; Opal Deposits; Great Gypsum Discovery, 210. The Mendocino Company's Mines; Montana Ore Shipments; Pacific Coast Appropriations by Congress; Coal in India; A Wonderful Well at Pioche, 214. How to Dispose of Oatmeal; A Common Illusion; Sewing Machines; Chopped Hands; Better than Gold; It is a Curious Fact, 215. The Miner's Song; Prospecting in Australia; The Iron and Copper Mines of Ireland; Reported Strike, 218.

LAND OFFICE ORDER.—The commissioner-General of the Land Office on the 1st inst. sent instruction to the Register and Receiver to carry into effect the Act approved March 31, 1873, providing for the joint entry of agricultural land to two or more pre-emptory settlers prior to a survey of the same. A legal sub-division may elect one of their number to make an entry and contract for a private conveyance back to the company pre-empting, when the patents are received.

BULLION YIELD.—During the month of January the Comstock (eight mines) yielded \$1,242,919.82. This was from Belcher, Buckeye, Crown Point, Chollar, Hale & Norcross, Savage, Sierra Nevada and Kentuck. During the month of February seven mines (the list above given, less the Sierra Nevada) yielded \$1,684,068.88—\$441,149.55 more than in January.

NARROW GAUGE.—The Contra Costa Farmers' Club, at their last meeting, passed resolutions in favor of building a narrow-gauge railroad from Walnut Creek to tide-water at Oakland, and recommended the county of Contra Costa to give a subsidy of \$200,000, on condition that it is extended from Walnut Creek to Martinez, and from Walnut Creek to Limerick.

A MILITARY LIBRARY is being established in San Francisco by a corporation, having for its object the purpose of acquiring, preserving and conducting a public library, to consist chiefly of books, magazines and newspapers of a military character.

THOMAS L. MOORE, well-known in mining circles in this State, committed suicide at Salt Lake City on the 2d inst.

ON FILE.—Letter from "Old Block," on the Grass Valley mines.

The Emma Mine Troubles.

Both the English and Scotch shareholders in the Emma mine are terribly exercised over the turn affairs have taken in connection with that property. The report of the directors, which we published last week cannot be looked upon as encouraging, and they have come to the conclusion that the sum paid for the mine was greatly in excess of its real value. The very pertinent question is asked can an English management thousands of miles away make the property pay an adequate dividend on the £1,000,000 capital employed? The English papers said that Mr. Warren Hussey's management partook too much of an amateur character, but they hope that the ability and experience of Mr. Geo. Attwood, the new Superintendent will set matters straight. At all events they want some one here in whom they can rely for correct reports as to the condition and prospects of the mine, and the money realized from the sale of ore.

It has come to light at the last meeting that outside parties had more correct and earlier information than did the directors who were disbursing the dividends. These statements were so contradictory that the directors did not know which to believe, but on several occasions the outside reports were confirmed, while those of the Directors were untrue. The Chairman of the meeting deplored the speculative character of the stock but could suggest no remedy as the large amount, and the large number of shares spread all over the country combined to make it speculative. There seems to be no doubt but that reports were withheld from the directors which they should have had. The great falling off in the character of the ore since the cave, was stated to be "a very peculiar circumstance," for that extracted previous to the cave was rich, whereas since then the ore was low grade. Professor Silliman's predictions as to the amount and value of the ore have proved fallacious and as far as the Chairman of the meeting could understand, the altered condition and prospects of the mine arise from the fact that the ore on the foot-wall of the vein was very rich while that in other parts was poor.

The reasons given in the Directors' report for the unfavorable aspect of affairs are very simple. Thirteen monthly dividends were paid amounting to £193,532, while the balance sheet shows that only £185,657 were available for that purpose, leaving a deficiency of £7,784. This has arisen from the flooding of the issue in June and the litigation with the Illinois Tunnel. The total amount of ore accounted for and raised by the company since taking possession as set forth in the accounts, amounts to a total of 9,862 tons, yielding a gross amount of £167,532, or £17 per ton; of this 2,790 tons were sold in Europe at a gross, not net, profit of £29 10s. per ton; 6,532 tons were sold at Salt Lake, at a gross price of £11 19s. per ton; and 550 tons were sold at St. Louis at £12 6s. per ton. The expense on the ore at Salt Lake City amounted to £56,303, equal to £5 16s. per ton; that on the 2,790 tons sent to Europe, £24,823 or £8 4s. per ton; and the London management expenses were stated at £1 per ton or £12,420. Thus after deducting the expenses of £29 10s. per ton, a profit of only £14 10s. was shown. It turns out that the net profit on the 9,862 tons raised by the company and the 2,800 tons said to have been raised by the vendors only paid £11 per ton. It is stated as a "remarkable and somewhat significant fact" that the amount of ore on the dump and the first shipments of ore after the mine had been purchased, were the only parcels producing anything like a first-class price.

The majority of the shareholders seem to be angry because the glowing terms of the prospectus were not carried out. One stockholder said he had been induced by promises of realizing 72 per cent. to invest, and proposed a committee of investigation to ascertain the causes of the non-fulfillment of these promises. Who ever heard of a property of any kind which was placed on the market that realized in full all the promises of the vendors, especially one which was sold at a fancy price as the Emma has. The mine has only produced 9,802 tons in 13 months, realizing under £36,403, or after deducting London management expenses £74,000, or less than 7½ per cent. for the 13 months. Moreover they owe the Illinois tunnel and Mr. Park £50,000.

The Directors have acknowledged that they

made a mistake when they paid the 13th dividend, and as some atonement, have voluntarily passed a resolution to reduce their own fees to half the present amount, with the addition of one per cent. on the net profits, but the remuneration in no case to exceed the amount provided by the by-laws. The Glasgow shareholders have held a sort of indignation meeting, at which one of them suggested a feasible way out of future difficulties would be to have three of the eight directors residents at the mines. The Glasgow shareholders hauled the directors over the coals, but expressed faith in the mine itself, and appointed a committee to attend to the interests of the shareholders. They sent two of their number to represent their interests in London, who were, in deference to their wishes, appointed by the London meeting members of the Board of Directors.

There seems to have been a great complaint among the stockholders about the London management expenses, which have been pretty heavy. They wanted imposing names among their Board, and the imposing names must of course be paid for being there. And even with all this, many of the owners of stock became prejudiced against this Board, and even hint forcibly at a "committee of investigation." The Board acknowledged they were deceived and that the reports received by them were not always correct. They took the trouble to send out a representative privately to the mines, but he died in New York, so that measure fell through. Now they have sent Mr. George Attwood. They have now come to the conclusion to give up the weekly telegram as well as the regular monthly dividend, the shareholders preferring a quarterly dividend. One member of the company wanted to appoint, in lieu of a committee of investigation, a committee of conference, to advise with the Directors in any practical measures in relation to the mine, but his motion was not carried.

The whole meeting passed off much more quietly than it was supposed it would, the majority of the shareholders professing their confidence in the mine if it was properly managed. This is also the case among outsiders, and the London Mining Journal states that respectable parties in London offer to lease the mine for 12 months at £10,000 pounds per month (equal to 12 per cent. per annum). The great difficulty has been to get correct information from the mine, but the general impression prevails that the difficulty has been overcome in the appointment of Mr. Attwood as Superintendent. It is to be hoped that the affairs of the Emma will be straightened out properly, as it is unquestionably the representative American mine abroad, and if failure ensues we will have great difficulty in again procuring the assistance of English capital in our mines. It is with sincere regret that we note the tone of many shareholders in this and other mines in England, which evinces a distrust of all Americans on general principles. But they should recollect that they seldom buy a mine without the advice of English engineers, and there are dishonest men on one side of the ocean as well as the other. We all regret the fact that unprincipled men have occasionally taken advantage of circumstances to appropriate money not their own, and have run mines in their own interest and not that of stockholders, and have sold worthless property, which they represented as valuable.

No doubt these things have been done in England as well as here, but it is unfair and unjust to condemn wholesale a class of people for actions committed by one of their number.

RAYMOND & ELY SUIT.—The Raymond & Ely vs. Hermes mining suit, is still going on in Pioche. The court is engaged as yet in taking testimony, which seems to be voluminous. The last accounts from there were to the effect that the jury—orsome of them—had been down the mine examining it. The suit has depressed the Raymond & Ely stock to some extent.

FREIGHT OVERLAND.—According to the report of J. C. Stubbs, Assistant Freight Agent of the Central Pacific Railroad 2,200,812 pounds of freight were sent East in February, making a total for January and February of 5,950,112. Among the items for February was 50,940 pounds of quicksilver.

THE HOMESTEAD LAW.—The new homestead law passed by the 1st session of the last Congress in the Senate, and on the last day of the 2d session in the House, was lost by being on the bottom of the pile and not being acted upon by the President in the time allowed.

IRON ORE of excellent quality has been found on Vancouver Island.

Railroad Management.

Importance of Mechanical Science.

One of the great difficulties encountered in the management of railroads is found in the efforts to keep the track free from broken or dangerous rails; and no engineering problem is more important to the railroad interests than that involving the production of a good quality of iron or steel for railroad purposes generally. Notwithstanding all that the Bessemer process has accomplished, this question is far from being satisfactorily solved. This is a matter, also, in which all who travel by rail have a vital interest. The dangers of such travel are diminished in about the same ratio as progress is made in the solution of this question. We have just read, in an Eastern Railroad journal, that the master of a section on the Boston and Albany Railroad, reports to the Company that he finds seven or eight broken rails on his section nearly every day; and that is certainly not considered a badly managed road. It makes one shudder to read such a statement, or to think of the possibilities of the accidents which are liable to occur from the least neglect of duty on the part of the section master.

A more reliable quality of iron is also as much needed for axles and wheels as for rails; and notwithstanding experiments have covered a wide range of conditions and brands, of both English and American make, still no definite, practical conclusions have been arrived at in which all can concur as to the most reliable brands.

There is also a manifest indifference or lack of even reasonable caution shown on the part of the many railroad managers, which, if it was more generally known, would no doubt exert a depressing influence on railroad travel. Too little attention is also given to the qualifications of employees for responsible positions; and there is also much difficulty experienced in finding suitable persons to fill such positions. There are too few young men who are especially educated for the business. Probably the technical schools, which are now being so rapidly multiplied, and becoming so deservedly popular, may make an improvement in this particular in the course of a few years.

Another trouble arises from the fact that really good men are not paid enough to compensate them for the years of study necessary to properly fit them for such a responsible profession—for profession it should be called. A young man engaged on one of our Western railroads, and who is evidently wide-awake to every practical application of science and knowledge to the operation of railroad machinery, writes to the Chicago Railroad Journal, as follows: "Good men are not paid enough, and for this reason they are driven to seek more lucrative positions. I must say that I feel that way myself, and I am now giving my leisure time to the study of higher branches of railroading. I must either have more money for the service I am now performing or I shall seek another position. I like the machinery department best; it is my forte; but I am poor and must look for a business that will pay me better."

It is very well known, to every observing man, that there are many young men, in all parts of the country, occupying similar positions, not only in railroading but in all other mechanical employments, who feel much as does the one above alluded to, whose ambition is surely worthy of high commendation.

It should be the ambition of every mechanic to be able himself, to solve all the problems involved in his especial art. If not all, he should certainly have a sufficient knowledge of them, to be able to appeal confidently to scientific men, and point out to them the application, improvement or information he desires.

For example, the railroad superintendent, or officer should be able to go back to the ore and understand, at least theoretically, every process and manipulation to which that ore, has been subjected until it arrives in his yard or shop, a finished rail, axle, or plate of steel or iron for his locomotive boiler. He should be able to analyze—or intelligently secure that service from another—any bar or plate, and determine correctly its character and fitness for the service desired.

There is a most reprehensible remissness in such particulars. At a late meeting in Boston, of master mechanics, gathered from widely different districts, it transpired that no one present could give a complete history, from the ore to the end of the career of a single plate, rail or bar of either steel or iron, which they had used; no analysis of any plate was reported; no con-

ception could be formed of the percentage of carbon, or sulphur, or phosphorus, that was present in any plate that had been used for boiler purposes; no analysis of any fuel was given, or of the water used in any single instance.

When we have master mechanics of scientific attainments and proclivities, who will fully investigate matters of such importance, in a systematic and connected manner, reliable and complete data may be attained which will be of practical importance; but so long as we depend upon uncertain and disjointed experiences and observations merely, and that information gained under diverse circumstances, we can never hope to make much progress even in such vital matters as pertain to the lives and safety of the thousands of our citizens who are compelled to spend much of their time in traveling by steamboat and rail car.

The time has fully come when science is not to be confined to professional men—especially so-called. The inspiration of science should reach every individual in the great army of skilled labor. This fact is acknowledged in our own State, by making the State University at Oakland a part of our common school system.

What industry is there that does not need the help of an engineer; and why should any laborer, skilled or otherwise, rest content with the mere ordinary manipulation of what is placed in his hands? But if any one desires to become progressive, his inspiration must be enlightened by study, either before or after he enters upon his calling. It should be the object of employers and the press everywhere, to stir up the intellect of men; for surely an educated, reading, thinking man is worth more to his employer than a careless, listless one, who has no care or thought beyond the present; and such a one should receive more for his services. There is neither sense nor justice in the idea that every man of a trade should receive the same rate of wages. Every employer knows that some men are worth from fifty to a hundred per cent. more than others. Then why not make merit—intelligence and skill—the standard of the value of labor?

The true mission of the laboring man will be fulfilled only when every individual shall employ his intellect and leisure in so improving his mind, that he may thoroughly understand the principles which regulate the processes and practice of his especial handicraft.

Germany has taken the lead in carrying out this idea. Her mechanics are more thoroughly educated than those of any other nation. This is the result of her technical schools, which have been established all over the land—free to all. It was this training—this combination of science with practice—that made it possible for the armies of Germany to make their late triumphant "march to Paris." Almost every man in the ranks was competent to fill the position of an officer. The German host was an army of engineers. Their patriotism and courage was enlightened by study, which gave their weapons an efficiency and power not possessed by their equally well armed enemy.

OUR EXPORTS.—The *Alta* has compiled some financial and commercial statistics for the first quarter of the year 1873 showing the amount and destination of domestic produce exported. By reference to the tables we find that 2,040 flasks of quicksilver were sent away, valued at \$141,325 against 2,737 flasks in the same time in 1872, valued at \$196,800. Of this 201 flasks went to Central America; 632 flasks to Mexico; 1,000 flasks to Australia; 100 flasks to China; and 2 flasks to British Columbia. We sent away during the quarter 554 tons of copper ore valued at \$33,208; 248 tons of silver ore valued \$37,461 and 501 tons of various other kinds of ore valued \$38,427. These ore shipments have fallen off from 1872 which is rather encouraging, than otherwise, since we now work most of our ore here instead of sending them away.

The *Celavene Chronicle* cannot recollect a time for several years when business in that section was so lively as it is at present. The revival of quartz and gravel mining has a beneficial effect on all industries.

A new quartz mill is being built at the mouth of Cañon Creek, Nevada county, by Messrs. Sann and Bleikie, of this city.

Emerson's Diamond Stone Saw.

We have made frequent mention in our columns of the efficacy of Emerson's diamond stone saw, and now have an opportunity of placing before our readers an engraving of this novel and peculiar instrument. The use of diamonds or carbons for drilling and dressing stone, suggested their employment for sawing the same material, and to those acquainted with the use of black diamonds or carbon, it is scarcely necessary to explain what can be accomplished in carving stone. The great object to be attained was to hold the diamond so firmly, maintaining the grip so that at least $\frac{1}{4}$ or $\frac{1}{2}$ the size of the diamond could be forced through the stone. This gripping device had to be so constructed as not to change or "buckle" the saw blade, in order to be effective. The diamonds, which are all of an irregular form, as nature left them, present sharp, rugged corners and jagged forms, but they had to be set uniformly, so as to give a small clearance for the saw, but not half that required in sawing wood, there being no fibre to stone. Their corners must project exactly alike, so that they will follow each other in their course, in order to leave a perfectly smooth surface. Sufficient has already been done to demonstrate that sawing stone with diamonds excels other processes.

Our engravings afford a clear idea of the device which accomplishes these effects, rendering a very detailed explanation unnecessary. Fig. 1, gives an edge view of a saw in its full size.

field holders of sandstone have repeatedly been crowded through the saw by hand, the saw cutting four inches deep at the rate of one inch per second, and that with only six diamonds cutting; and it is asserted that not a diamond has ever come loose, or any part of the fastening given away. The use of these black diamonds is varied and effective, for they have been applied to glass cutting, for turning of solid emery wheels (and the solid emery wheel cuts every other substance known in the mineral or metal kingdom); for dressing burrstones, and for rock drilling and dressing, including the hardest flint, quartz and granite, and lastly in sawing stone.

The patent adjustable holders are manufactured by Emerson, Ford & Co. of Beaver Falls, Pa., who offer State, county or city rights for sale.

University of California.

At the last meeting of the Board of Regents of the State University on the 1st inst., the contract was let for building the College of Letters.

The lowest bid was \$83,750, the building to be completed Sept. 20th 1873. A peculiar circumstance connected with this is that the successful contractors have assumed the Committee that whatever profits they

derive above the cost of the structure they will donate to the University.

President Gilman announced the following valuable donations to the University:

From George M. Blake, ten acres of land adjoining the Berkeley site. The land is valued at about \$1,000 an acre.

From D. O. Mills, a rare cabinet of mineral ores, fossils, stones, etc., being a collection of

DIAMOND HOLDER.

EMERSON'S PATENT STONE SAW.

Fig. 2, is a section in perspective. Fig. 3, represents the diamond holder, of which A, exhibits the appearance of a side; B, a perspective view; and C, D, and E, the different shapes of diamonds used. The solid steel holders are made adjustable and interchangeable in the saw. It is claimed that in gripping the diamond they hold its jagged sides imbedded with such firmness that the cast-steel will be torn asunder before the carbon will work loose. The mode of confining the holders, it is also asserted, does not in any way tend to change or buckle the blade. The device is equally applicable to circular and reciprocating saws; it was patented by Mr. J. E. Emerson, the inventor of inserted-tooth saws for lumber.

A test of the operation of this system was made with a 12-inch circular saw, carrying six diamonds, and running on an average of 2,500 revolutions per minute. A piece of Italian marble three inches thick and four feet long was sawed through in one minute; and of Berea grindstone, three inches thick and five feet long, in one minute. The same saw has been on eight exhibitions, sawing various kinds of stone, including Quincy granite, and it is said that not a diamond has even moved, nor did they show under the magnifying glass, any perceptible wear. It is, of course, designed to use a small stream of water either on the saw or in the kerf while it is cutting. In marble cutting it is said that the diamonds cost less than the iron blades and sand. The marble dust is saved pure, while in sand sawing it is lost. This invention is also applicable to turning round on irregular forms. The tests that have been made were far more severe than would be required of a saw in practical use. Irregular

many years by C. D. Voy, and showing especially the geology and mineralogy of the Pacific Coast; number of specimens, 7,927; cost, \$5,000.

From Michael Reese, the library of the late Dr. F. Lieber, consisting of 3,000 volumes; cost, \$2,000. It is also stated that Mr. Reese will purchase a large and select library for the University when he is in Europe, where he intends making a visit shortly.

Donation of \$1,500 from Captain W. H. Reynolds, \$500 from C. W. Howard and \$500 from Henry D. Bacon for the purchase of educational apparatus, diagrams, maps, books, etc.

From the Mechanics' Institute a collection of Japanese minerals and metals of industrial arts.

From Louis Janin, a contribution of mineral ores.

From S. F. Butterworth, bound volumes of the New York Times from its first number to the close of the war.

From H. J. Booth & Co., of the Union Iron Foundry, a five-stamp battery and mill, with all the latest improvements. We hope this last gift will form a nucleus of a fine and varied set of mining machinery for the use of the School of Mines.

The committee appointed on the Medical Department Subject presented a report recommending the establishment of a series of chairs in the department to be filled by the Board. They recommend that in perpetual recognition of the munificence of Dr. H. H. Toland, one of the chairs in the Medical Department, to be designated by him, shall be known as the Toland Professorship; and further, that a suitable inscription be placed upon the Medical Hall which he has given, designating it as the Toland Medical Hall.

PATENTS & INVENTIONS.

Telegraphic List of U. S. Patents Issued to Pacific Coast Inventors.

(REPORTED OFFICIALLY FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch, Dated Washington, D. C. April 1st, 1873.

FOR WEEK ENDING MARCH 18th, 1873.

CAR COUPLING.—George Withington, of Ione City, Cal., and Frank F. Taylor, S. F., Cal. CANNELSTICK.—Amos E. Rogers, La Grande, Oregon.

REISSUE.

LUBRICATOR.—William T. Garratt, S. F., Cal.

"The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Note.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

The Vienna Exposition.

The following gentlemen have been appointed by the President to attend the Vienna exhibition, under the joint resolution of Congress, approved February 14, 1873:

Practical Artisans—N. M. Lowe, Mass.; Chas. Davis, Pa.; Jos. V. Meigs, Mass.; R. B. Lines, D. C.; John R. Nurse, Md.; Louis J. Hinton, N. Y.; Lyman Bridges, Ill.; George A. Stanberry, Ohio.

Scientific Men—E. N. Horsford, Mass.; J. Lawrence Smith, Ky.; Lewis M. Rutherford, N. Y.; Peter Collier, Vt.; R. H. Thurston, N. J.; L. J. Boeck, Va.; John A. Warder, Ohio.

Honorary Commissioners—J. Dawson Coleman, of Penn.; Thomas Nast, New Jersey; Dr. J. W. Hoyt, Wisconsin; J. H. Speed, Alabama; Frank Drexler, Alabama; A. McDonald, Arkansas; J. Newman, California; George W. Parker, J. K. Kilbourn, Joseph Plant, E. S. Wheeler, Connecticut; W. C. Bibb, Edwin D. Newton, Georgia; J. M. Gregory, Allen W. Stolp, Illinois; Jesse S. Brown, A. Ballweg, Indiana; James A. Williamson, A. F. Hofer, G. T. Carpenter, Samuel F. Cooper, Iowa; Henry Tarstedt, Kansas; C. F. Carpenter, Kentucky; Frank Morey, Henry Vignand, Louisiana; J. Edwin Therwan, Maine; W. T. Walters, Maryland; J. D. Philbrick, Nelson L. Darley, L. F. Melten, Henry Marian Howe, D. A. Goddard, Louis Weisbein, Massachusetts; James Pirney, Henry C. Louis, Michigan; Col. Edward P. Jones, Augustus Senige, Mississippi; H. C. Creveling, G. H. Koch, Charles A. Smith, Missouri; H. J. Wisner, John A. Van Winkle, John Duncan, G. Dewitt, N. J.; Prof. Davies, G. Saner, I. W. Rogers, Wm. C. Ginnell, J. H. Sherwood, Francis A. Stont, George W. Silcox, R. W. Raymond, Jackson S.

Schultz, Douglas Taylor, George Thnrer, New York; W. C. Kerr, North Carolina; Montgomery Phister, O. G. Leopold, Freeman Thorpe, G. Mandenhall, Ohio; Charles E. Smith, Oregon; Howard Painter, Thomas Beauer, John Shion, Henry D. Moore, David Brooke, Joseph Wharton, J. Milliken, Charles M. Nes, Pennsylvania; Elisha Dyer, Rhode Island; Samuel Tate, L. G. Dupre, Tennessee; C. S. Morrill, Levi K. Fuller, Vermont; Moses P. Handy, Virginia; J. H. D. Debar, West Virginia; Geo. W. Smalley, J. Russell Young, Benj. R. Winthrop, Charles K. Tuckerman, Dr. Thomas Binkler, at large; E. M. Hamilton, Colorado; Richard K. Evans, Richard D. Cntis, David Edes, Joseph Enthoffer, Arthur H. Brown, District of Columbia; James M. Cavaoagh, Montana; Adolph Guttman, New Mexico.

BOILER INSPECTOR.—James Hillman has been appointed Boiler Inspector for this District. Mr. H. was for some time Superintendent of the shops at Mare Island, but latterly has been overseer of machinery for the Pacific Mail Steamship Company.

GILROY is the seat of the latest quicksilver discoveries, three "chimneys" having been found recently.

THE JURY on the Raymond & Ely suit has visited the mine for the purpose of examining it.

It is proposed to establish an artificial ice manufactory in this city shortly.

MAPLE SUON is now being made in Sierra County Cal.

The Miner's Song.

BY J. O. SEVERANCE.

I toll in "vein"—the life I "lead"
Up here in Deadwood Canon,
Will never pay unless with speed,
I "pan out" a com—"pan" ion.
I "struck" a "specimen" that cuttle—
Her "lead" I've been "a-trying"
Since first the beauty of the "hutes"
Came down my "race" s-racing.

The "color showed" upon her cheeks,
Her eyes "cropped out" with frolic;
Her hair sprayed out in golden streaks
On high, like my "by"—dreadful.
To test her worth I made "sassy";
Found her o're stubborn, rather;
And under par. I went away—
Not far—to see her father.

I sought him with a bitter green;
His love for gold was mighty.
The only "Cupid" he had known
Was winged with s-t-y-t-y.
"What 'prospects' have you got, young man?"
Said he with scornful titter;
And when I said, to every "pan"
A bit, he was less bitter.

I "staked my claim" so very bold,
It warmed his heart of "houlder";
He said, let wedding bells be tolled!
And then I went and told her.
We "made the rifle" quick, you bet!
For I believed it better
To have the "record" made, while yet
The "parent vein" would let her.

Now she is won—we both are one;
Of love and gold the hoarders;
We swim in happiness and fun,
Content, like Swinney's hoarders.
And in the "cut" she "kisses"
She places—"just to please pa!"
I may as well "own up the cheese"—
A little nine pound "chips"—

—Call.

An Important Invention.

A short time since we made mention of an invention by Mr. D. Morey, of Watsonville, of an attachment to threshing machines, by which the straw may be used as fuel for running the engine.

We recently, in company with a number of scientific gentlemen, had the pleasure of witnessing a test of this invention, on the premises of Mr. H. W. Rice, a well known machinist at Haywood, which gave the utmost satisfaction, and promises to be the most economical machine that can be used on a farm. The object of this invention is to utilize straw as fuel for the purpose of generating steam, instead of wood or coal. The attachment is exceedingly simple in its construction, made of heavy sheet iron, and weighs when completed only 75 pounds. All that is necessary to put the machine in working order is to open the furnace door, attach the machine by a hasp to the door catch, and two small rods of iron to the hinges of the door, when it is ready for operation. This may be removed whenever desired in a few minutes time. About three hundred pounds of dry wheat straw having been brought to the machine and a feed fork full thrust into the furnace which was cold, (not having been in use for some time), the fire was started and in precisely thirty minutes, steam was raised, in forty minutes from starting the fire, the steam gauge indicated forty pounds pressure, and in forty seven minutes, seventy pounds.

At the expiration of one hour but 150 pounds of straw had been consumed; in the meantime the power had been used running two engine lathes, an iron planer, drill press, and grindstone; the pump being put on the boiler was quickly filled with water to its utmost capacity without diminishing the pressure. The machine having been tested to the satisfaction of all present, Mr. Rice, desiring to operate his engine lathes, planer, drill press, etc., kept up steam for six hours, consuming in that time only 200 pounds of straw, proving that one ton of straw per day would be amply sufficient to run the thrasher. Even were five tons of straw per day necessary it will be a vast saving to the farmer, who invariably burns the bulk of his straw to get it out of the way.

Straw has been proved to be a superior fuel for the threshing engine, when properly used; it makes a very hot fire, the whole interior of the furnace being filled with a roaring flame which sweeps through the flues and heating the water in a remarkably short time. To run a threshing machine it requires only one-twentieth of the straw from a separator, and a boy twelve years of age can attend to the straw feeder with ease, or for that matter the engineer will have no difficulty in attending to the feeder himself.

There are also many advantages from using straw; there are no sparks, and of course there is no need of a "spark arrester"—no danger of setting stacks or stubble on fire; furthermore, the fire from straw does not burn the iron as does that from redwood; there being no cinders it is very little trouble to clean the flues.

Mr. Morey has expended considerable time

and money in experimenting, and is now rewarded by the invention of an appliance, that will revolutionize the threshing of grain, and save a vast amount of money yearly to the farmer in the way of wood, especially in localities where wood is scarce. Mr. Morey procured his patent through the agency of Dewey and Co., and is now prepared to receive orders for his attachment.

Prospecting in Australia.

The Rev. W. B. Clarke has delivered an address to the Royal Society of New South Wales, at their late anniversary meeting, on their diamond-fields. It seems there are now twelve localities in Australia known to be diamondiferous. Of these five are in New South Wales, five in Victoria, and two in South Australia. The latest discovered sites are those of the Hoxton river, those of the Macquarie, a little below Bathurst, and those at the head of the Fish river, which is, in fact, the Macquarie. Thus the last named stream bears diamonds, at intervals, for the space of many miles. The idea that diamonds will lose their commercial value, if found in such abundance as at the Cape, is no longer prevalent. Castellan, indeed, predicts "that at the end of the present century the diamond will be worth only 20 per cent. of its value in 1800." The diamond, however, is not intended for a mere ornament—for a simple article of luxury. It has other and far higher functions to perform. By the method of cutting rocks by means of the diamond drill—which was first used on the Bologna railway, in Italy, and afterwards in the excavation of the Mont Cenis tunnel—means have been found for utilizing and disposing of the small stones, which constitute by far the greater product of all diggings. It is probable, therefore, that when new fields have been discovered, when every fresh return shows an increase in the value of exported diamonds, that they will come into far more active and general use. Mr. Daintree, Agent-General for Queensland, who was wrecked on the Southern Coast of Africa, on his voyage to Britain, noticed the prevalence of an agate conglomerate from the drift of the Vaal, which reminded him strongly of a like conglomerate on the Gilbert river, where he had been engaged in exploring. Since that time the Government has offered a reward for the discovery of a diamond field in Queensland. It is satisfactory to know that the production of gold in Australia is also on the increase. As regards the ill-starred expedition to New Guinea—while deprecating the rashness and precipitancy of the undertaking—Mr. Clarke recommends prospecting nearer home. Even in the neighborhood of the gold fields there are many "reefs" as yet untouched, and there is every reason to believe that some will be productive. It must be born in mind, too, that wherever there are certain rocks of igneous origin, such as diorite, felspathic veins, or felstones, in company with pyritic minerals, it is certain that the precious metal is not far off. At the same time miners have begun to realize the truth that many theoretical views relating to the nature of gold-bearing rocks are only partially reliable. For example, as a rich reef has recently been struck at a depth of 800 feet, those who hold the theory of shallow reefs will have to give up their views.

Of tin and copper there are sources now considerably drawn upon, and likely before long to affect the English market. It seems that these metals are as abundant in Australia as in Cornwall. Respecting the development of copper, its appearance in great abundance in the far western interior has been made known during the past year. Captain Sturt, when pursuing his explorations beyond the Darling, found an inhospitable desert, where there was nothing but low ridges, level plains, and scanty vegetation. The commissioner of Crown lands in the Albert District, has since notified to Mr. Clarke the presence of copper and magnetic iron ore in large quantities throughout this desert waste. It is hoped that both the Government and the community will give their utmost attention to the practical management of these treasures. Errors will only lead to great difficulties and corresponding inconvenience. We may now look forward with confidence to the time when the Courtandie, Malia, and Coonharaba Ranges of the Barrier will swell the mineral riches of Australia. A very rich conglomerate of gold, silver and copper seems to have been discovered in Gympie. Copper has also been found in Maneero, alloyed with antimony. Mr. Clarke has a specimen from Bathurst with eighteen ores and minerals combined. But he adds, "in general such combinations are not promising." Among other specimens forwarded from Australia to England there is a beautiful sample of the precious opal, taken from a hill in Secondary Rock near the head of Bulla Creek. Whether or no this mineral will ever come to be profitable is still doubtful; but it is worthy of notice for its lustre. The result of Mr. Clarke's investigation is noble in the extreme. He has often stated Eastern Australia to be one vast field of mineral wealth; we have now evidence to the truth of his statements. From north to south, and from the coast to the 141st meridian, the western boundary of New South Wales, we know that besides the more valuable metals—gold, copper, tin and lead—there is in many places an abundance of coal, and other minerals of less local importance.—Iron.

The Iron and Copper Mines of Ireland.

The iron and copper mines of Ireland are nearly all found in the South. The mineral wealth of County Cork exceeds that of any other county of Ireland, as will be seen from the following facts which we have compiled from the most authentic sources. The Cooshen mine was worked so extensively thirty years ago, that solid copper ore to the value of £20,000 was raised and sold. There are six parallel lodes in this mine, within a distance of 150 or 200 fathoms, and they are a continuation of the great belt or zone of copper lodes traversing the district from Aughdown to Brow Head. Cargoes of ore from this mine have been sold at Swansea at £38 per ton. To the east of Cooshen is Ordentenant mine. An adit level was commenced many years ago in this mine, and driven north in mineralized ground, with a view of intersecting the lodes of Cooshen, but it was stopped short when within a few fathoms of the principal lodes. To the east is Ballycummish mine, which has been worked for a number of years, and has been sunk to a depth of 210 fathoms. Upwards of £50,000 worth of copper ore have been raised and sold from this mine. A prospectus has recently been issued for the formation of a company for working Ballycummish and Cooshen mines, in which it is stated that such an undertaking is practically beyond the reach of private enterprise, and that there are now in the former mine about 2,000 tons of ore in stopes ready to be raised. About a mile to the east of Ballycummish is the celebrated Old Andley or Cappagh mine. It is furnished with powerful machinery, and is within half-a-mile of a shipping place. The main shaft has been sunk to a depth of 115 fathoms, and has produced £60,000 worth of copper ore. Samples of the ore recently assayed by Messrs. Johnson and Son, assayers to the Mint, yielded 87 ounces of silver to the ton of ore, and the aniferous copper ores yielded 20oz. 5dwts. 17grs.; 12dwts. and 12½dwts. respectively per ton of ore. The East Cappagh mine is not the same run of lodes as that of Cappagh, and yields a rich percentage of silver and copper. The east shaft has been sunk about 50 fathoms perpendicular, and the west shaft 30 fathoms; there is, therefore, a block of the lode standing between the two shafts, 40 fathoms high and 36 fathoms long; also a block of ore ground 35 fathoms high to the west of the west shaft.

The great chain of mountains beginning at the Mizen and Three Castle Heads, and facing the Atlantic Ocean, forms a copper zone, or belt of lodes, for a distance of between twenty and thirty miles; and in every place between the extreme points, where trials have been made, rich copper ore has been discovered. The Mizen Head lodes strike through Collins's Mine, near Goleen, in which an adit level has been driven a considerable distance on the course of the lode, and a main shaft sunk under the adit thirty fathoms. The copper lodes at Three Castle Head crop out in the cliffs, and contain fine specimens of yellow copper ore, quartz, etc. Dhorode copper mine, to the east of Three Castle Head, was opened in 1843, and several cargoes of yellow copper ore were raised and sold. On the eastern slope of the mountain range a valuable deposit of the sulphate of barytes has been discovered. The next are the Baudon Barytes Mines. The barytes in this mine is pure sulphate of baryta, thousands of tons of which have been shipped to England. At a short distance south of the engine-shaft the barytes lode is intersected by an east and west copper lode; and indications of copper ore have recently been observed in contact with the barytes lode, near the engine shaft. The foregoing are a few facts connected with the mineral resources of Ireland. From this, and similar testimony, which has from time to time been disclosed, it is evident that Ireland abounds with mineral wealth; and we venture to hope that at a time not far distant the people of Ireland will exert themselves, and utilize their own natural resources, instead of being dependent upon other countries for those things which they themselves possess.—Iron.

REPORTED STRIKE.—The Territorial Enterprise, of the 29th, says: A report is current that a fine body of ore has been developed on the 1,600-foot level of the Savage mine. The width of the deposit found is variously given. Some say it is four feet in width, while others will have it no less than twelve feet wide. Be the width what it may, it is pretty generally conceded that a really valuable deposit of ore has been found. A gentleman yesterday informed us that three assays were shown him, that were said to have been made from ore taken from the new body at random, the lowest of which was \$260 per ton. If they have plenty of ore that will assay \$60 per ton, we will say nothing about the little \$200 extra. We hope that all that is said and surmised about the development may prove true, but these things must be taken with a few grains of allowance; particularly at a time like the present, when men's wishes are not only the fathers of their thoughts, but also of most of their reports.

CROWN POINT.—The Crown Point Mining Company shipped on the 27th, to London, England, through Wells, Fargo & Co., thirty-two bars of bullion, valued at \$96,397.90.

DEWEY & CO.,

American and Foreign Patent Agents, Publishers of the Mining and Scientific Press, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing. The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applications which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency. The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by the extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

Betts's Capsule Patents.
To prevent infringements, notice is hereby given, that
Betts's name is on every capsule he makes for the principal mer-
chants in England and France,
thus enabling vendor, purchaser, and consumer not only to
identify the genuineness of the capsule, but likewise
the contents of the vessel to which it is applied.
The LORD CHANCELLOR, in his judgment, said that the
capsules are not used merely for the purpose of the orna-
ment, but that they are serviceable in protecting the wine
from injury, and insuring its genuineness.
MANUFACTURERS:—1, WHARF-Road, CITY-ROAD LON-
DON, AND BORDEAUX, FRANCE.

SITUATION WANTED.
A Thoroughly Practical and Theoretical
Miner, acquainted with the mining business in all its

Varney's Patent Amalgamator.
These Machines Stand Unrivaled.
For rapidly pulverizing and amalgamating ores, they
have no equal. No effort has been, or will be spared
to have them constructed in the most perfect manner
and of the greatest number now in operation, not one has
ever required repairs. The constant and increasing de-
mand for them is sufficient evidence of their merits.
They are constructed so as to apply steam directly
into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:
The pan being filled, the motion of the muller forces
the pulp to the center, where it is drawn down through
the aperture and between the grinding surfaces.—
Thence it is thrown to the periphery into the quicksilver.
The curved plates again draw it to the center, where it
passes down, and to the circumference as before. Thus
it is constantly passing a regular flow between the grind-
ing surfaces and into the quicksilver, until the ore is
reduced to an impalpable powder, and the metal amal-
gamated.
Setters made on the same principle excel all others.
They bring the pulp so constantly and perfectly in con-
tact with quicksilver, that the particles are rapidly and
completely absorbed.
Mill-men are invited to examine these pans and settlers
for themselves, at the office, 229 Fremont Street,
San Francisco.

Nevada Metallurgical Works.

LEA & PERRINS'
CELEBRATED
Worcestershire Sauce.

Declared by Connois-
seurs to be the only good
SAUCE
Caution Against Fraud.
The success of this most
delicious and unrivaled
Condiment having caused certain dealers to
apply the name of "Worcestershire Sauce"
to their own inferior compounds, the public
is hereby informed that the only way to
secure the genuine is to ask for LEA &
PERRINS' SAUCE, and see that their names
are upon the wrapper, label, stopper and
bottle.
Some of the foreign markets having been
supplied with a spurious Worcestershire
sauce, upon the wrapper and labels of which the names
of Lea and Perrins have been forged, L. and P. give
notice that they have furnished their correspondents
with power of attorney to take instant proceedings
against manufacturers and vendors of such, or any
other imitations by which their right may be infringed.
Ask for LEA & PERRINS' Sauce, and see name on
wrapper, label, bottle and stopper.
Wholesale and for export by the Proprietors, Worces-
ter; Croese & Blackwell, London, &c., &c., and by
Grocers and Oilmen universally. 15v24-1f

EUCALYPTUS.
The attention of the Medical profession is respect-
fully called to the following preparation of this new reme-
dial agent. Eucalyptus and its preparations have been
found useful in obstinate cases of Intermittent and Malar
Fever, often supplanting the use of Quinine. The
paroxysms of Asthma and Catarrh are greatly controlled,
and in various Kidney diseases and Catarrh of the Blad-
der it seems to act like a specific.

FLUID EXTRACT EUCALYPTUS.
This extract represents in a concentrated form the
medicinal effects of the leaves of Eucalyptus Globulus
THE ELIXIR OF EUCALYPTUS.
This compound presents the properties of the leaves
in a palatable form and elegant appearance. Dose—
One tablespoonful, to be repeated as often as the case
demands.
Cigarettes of Eucalyptus Globulus, useful in
Asthma, Difficulty of Breathing, Incipient Pleurisy, etc.
Prepared and sold by JAMES G. STEELE & CO.,
Chemists and Apothecaries,
No. 521 Montgomery St., between Clay and Commercial,
San Francisco. no28

THE EAGLE HAY PRESS.

The above is a correct representation of this re-
markable **EAGLE HAY PRESS**, the invention of J.
A. McCallum, of Illinois, to whom Letters Patent were
issued Jan. 10th, 1865, and July 24th, 1866.
Several years were devoted by the patentee to the per-
fection of this powerful press, and its unprecedented
sale in the East induces the proprietors to introduce it
into California and the Pacific States.
All who have seen or used these presses pronounce
them superior to anything used heretofore. The power
is applied by means of two levers, and it will be seen
the power increases in ratio to the resistance, as the
levers approach a horizontal position the power can
scarcely be estimated. It is not only a powerful press,
but has the advantage of being cheap, and also simple,
therefore not liable to get out of order.

Three men with one horse can bale from TEN TO
FIFTEEN TONS PER DAY, each bale weighing 250 to
300 pounds. It obviates all a cessity of beating the
hay before pressing. On account of its great power it
is well adapted for pressing HYDES, BAGS, WOOL OR
COTTON. When a bale is pressed and fastened the fol-
lower runs down of its own weight, and the bales can
be taken out on either side. On April 18th, 1871, this
Press was tested at the State Agricultural Hall, Sacra-
mento, and stood the test of a bale of wool, 550 pounds.
Ref. reno, Maj. Rob't Beck.
We have added to this Press this season an improve-
ment (patented) which does the stamping, dispensing
with men to tread down the hay in the Press, facilitat-
ing the operation, and saving much hard work. The
additional cost being but \$25, paying for itself in labor
saved in a week.

These Presses are now manufactured in San Francisco
by the
Kimball Car and Carriage Manufact'g Co.,
Who are the Proprietors on the Pacific Coast, and will
endeavor to have a supply constantly
on hand.
12v5-2am-3m-2ts

Polishing and Fluting Iron.

This new invention takes the place of two articles
needed in nearly every house. As a **POLISHING IRON**
it has no superior. The part used for fluting is made
of brass, and highly polished. A Receipt for making
FRENCH GLOSSING STARCH, that gives a superior polish,
goes with each iron. The Polishing Iron and Fluter,
being in one, are both heated at the same time. We are
now prepared to furnish them in quantities to suit.
Price, \$3.

Rivers, Lakes, Railroads, Mines and Mining Districts
throughout the Territory, and all Government Surveys
made to date. Price, mounted, \$8; Pocket form, \$5.
Mailed to any part of the United States, on receipt of
price, by A. L. BARNETT & CO., 721 Market street,
San Francisco, Cal., or by B. A. M. FROISETH, Pub-
lisher, Salt Lake City, Utah. 10v25-1f

[Continued from Page 213.]

Though large bodies of good ore have been in sight for some time in the deepest works, it is only within the last day or two that the very high grade metal has come in.

WASHOE.
HALE & NONOCOS.—Gold Hill News, March 29: About the usual amount of good ore is being extracted from the ore-breasts on the 800-ft. level, also the 1,400-ft. and 1,600-ft. levels, which continue to look and yield finely. A new section has been opened in the north or engine winze at the 1,600-ft. level, where the ore body has opened out 12 ft. in width of fine quality. The raise on the ore vein struck at the opening of the 1,700-ft. station is making good headway, the ore gradually widening out from 3 ft. where it was found until it is now 11 ft. in width and of excellent quality.

SAVAGE.—The main shaft drift on the 1,600-ft. level is still driven energetically ahead, the drift progressing at the rate of 5 ft. per day. The first cross-cut west from this drift, 150 ft. south of the incline, during the week cut through what appears to be the southern terminus of a body of \$30 milling ore, 7 ft. thick.

CON. VINOIMA.—Work in the prospecting cross-cut on this level is nearly suspended for the present on account of the intense heat encountered as soon as the shaft gets to a few feet away from the main drift. The shaft is now down 284 ft. below the 500-ft. level.

GOLD & CURRY.—The north drift from the main east drift on the 1,500-ft. level is still driven ahead, the face in fine favorable looking quartz, but no ore of any consequence. The main south drift on the 1,600-ft. level to connect with the north drift on the same level from the Savage, is in excellent progress, the rock in the face working finely.

CHOLAR-PORT.—Daily yield 150 tons of ore, the assay value of which is \$35 per ton. Work has been resumed in the different ore-breasts of the old works which are both looking and yielding well.

BROCKEY.—The Hope mill was again started up last Monday, and has been steadily running on ore from the mine since that time. The new ore-breasts in the south drift at the first station are opening out finely, and promise a goodly yield of ore for the future.

JULIA.—The cross-cut south from the main west drift is in 69 ft., the face in good ore, the ore vein having gradually opened out from 18 inches, where it was first struck, to 18 ft. in width, and giving promise of a fine development.

CHOLAR-PORT.—The new cross-cut from the main tunnel to connect with the old upper works is up 100 ft., cutting through, during the week, a body of excellent ore.

SURRO TUNNEL.—Total length, 3,745 ft. Good progress is made with the heading. The face is in hard, dry rock, which works well.

BECKER.—The main incline is down 90 ft. below the 1,200-ft. level. The main drift south, at this level, is in 318 ft. from the Crown Point line, and the drift north to meet it, from the incline, is in 184 ft. The main south drift, at the 1,400-ft. level, is again being pushed ahead. The cross-cut east from it is in 59 ft. with about 25 ft. of good ore. About 60 tons per day comes from this level through the Yellow Jacket shaft.

CAWON POINT.—The yield of the week was less than usual, by reason of repairs to the holding arrangements. All the ore-breasts are looking as well as usual. The main east cross-cut at the 1,300-ft. level is discontinued, having reached the east wall, with a good showing of ore all the way. The floors at this level are looking splendidly. The south drift at the 1,400-ft. level is being timbered. The main incline is now down 117 ft. below the 1,400-ft. level, in dry, hard rock.

YELLOW JACKET.—Work at the 1,500-ft. level, east drift, is still delayed by reason of too much water. Drift north at the 1,400-ft. level going ahead with very favorable indications.

ALAMO.—The shaft is down 42 ft. the full size still in good ore, fair progress being made, although the ore requires continual blasting.

WHITE PINE.

WARD BECKER.—White Pine News, March, 29: For a long time many miners have argued, that the pitch of the ore body on Treasure Hill was easterly, but until the work done on the Edgar shaft, one of the locations embraced in the Ward Becker Con., the majority steadily adhered to the theory that the lead pitched west. Their conclusion was founded entirely on surface work, which showed a broken mass of limestone evidently laying in a horizontal position, that plainly was the result of some great upheaval which at some remote period has broken up the immense mountain, leaving a mass of debris or broken rock on its outer or western slope. The fallacy of this theory has been fully and fairly demonstrated by the workings of the present mine. Entering at a drift below Main street, one west from the Edgar shaft, we pass through first the broken masses of limestone, mentioned above, which lay flat, and thence in through this formation a distance of 20 or 30 feet, we came to rock a little more solidified, where we notice the layers or seams pitch to the west; further on the rock begins to assume a permanent and solid character, when we commence to discover patches of ore here and there, with the ledge pitching due east, inclining downward at an angle of from 20 to 30 degrees.

Following down an incline we strike the first level, a distance of 121 feet from the surface, which leads us into the Edgar chamber. This famous chamber is some 40 feet in height, and a vein of ore has been found to the width of 40 or 60 feet. The Big Smoky mill was run on the ore taken from this chamber during last summer, and the amount is not yet exhausted. Going down from this level in the Edgar shaft, which commenced at the surface, 141 ft. above and has been sunk to the depth of 151 ft., cutting in its downward course one of the most permanent appearing veins of ore ever found in Treasure Hill. Work is still being prosecuted in this shaft to a lower depth. Proceeding due east, we arrive at the first winze, sunk now a depth of 20 ft., and ascending a body of ore of the same width, 40 ft., as found in the Edgar chamber.

There is now a large dump of first-class ore, averaging \$60 and \$70 per ton, which is only awaiting good roads to be transported to the mills for crushing. Work on the Hidden Treasure and other mines belonging to this company is being pushed forward with energy and good results.

Idaho.

SOUTH CHARIOT.—Owyhee Avalanche, March 22: No rich body of ore has yet been reached in either of the drifts, but we expect that something good will be struck in the 8th level before our next issue. The 6th level drift has just crossed a large slip, and a heavy volume of water is coming out of the vein, plainly indicating a large vein ahead.

MAHOGANY.—The slopes above the 6th level, in this mine are now yielding a fine quality of ore. The 7th level is opened for a distance of 114 ft. south of the shaft, timbered ready for stoping and carrying splendid looking ore in the face of the drift. The Cosmes mill is running on Mahogany ore.

RED JACKET.—This mine is at present one of the most promising in camp, and continues to open up well. The winze from the 1st to the 2d level is being put down rapidly, and shows big grade ore. The slopes are looking well and show a large vein. The adit level is being pushed ahead as fast as possible.

MINNESOTA.—The 1st, 2d and 3d levels are being pushed north with the utmost activity. The first is in 165 ft., showing good ore for the last 30 ft.; the 2d is in 300 ft., displaying fine looking ore in the face of the drift; the 3d is in 165 ft., the ore looking about the same as in the 2d. The 3d level is now down 68 ft. The ore is being hauled to the Owyhee mill.

INA ELMORE.—This mine shows much improvement in the lower levels, and considerable ore is being raised daily. There is every encouragement to expect

that an extensive body of rich ore will be opened out in the next level of this mine. The ore in the lowest workings shows more free gold than has any of the upper levels, since the famous rich deposit near the surface.

GOLDEN CHARIOT.—We believe that no work, except by contract is being done in this mine at present.

ILLINOIS CENTRAL.—This mine continues to yield a rich quality of ore.

Montana.

NEW DISCOVERY.—Rocky Mountain News, March 19: We learn that a very gravel bed, running north and south for some 20 miles, bearing every evidence of having been the old channel of the Missouri river, was recently discovered, 10 miles east of Diamond city, known as Gravelly Range, and that several men have been at work sinking shafts and prospecting with every evidence of a rich placer mine. Shafts to the depth of 70 ft. have been sunk through the gravel without yet finding bed rock, owing to water rising and driving the workmen out of the diggings. A good working prospect has been obtained, and the discoverers and owners propose to open up the claims and turn a ditch in from Deep Creek this season.

KEARAGE.—Montanian, March 20: The new Co. have been hitting ore from this lode, at Summit, nearly all winter, and at no time have been dependent on proving the lead a good one but a few days since their hopes were considerably brightened on washing a panful of crevice dirt, to find \$192 of fine gold as a result of the wash.

Philipsburg Correspondence New North West, March 22: There are two tunnels being driven vigorously. One is located near town by McLeod, Duffey, Kussell and others. They are running on the 8-hour system. The tunnel is in nearly 300 ft., and the prospects fair. The Flint Creek Tunnel on Frost Creek, running through Trout Hill, is in over 80 ft., and has entered a large vein over 70 ft., and only one wall is found yet, so the width of it is not known.

Vienna World's Exposition.

[From Our Correspondent at Vienna.—G. K. VEREL.]

On my arrival in New York I called at the office of the agency of the Vienna World's Exposition, for the purpose of securing space for a mineral collection from the mining districts of Utah Territory. There I was informed that quite a number of applications for space for American articles had been made, but California did not take a prominent part in it. It seems that neither General Van Buren, nor the Governors, nor the press were much engaged in encouraging the representation of our industry in the World's Fair. The first that we heard of Van Buren's circular was through the MINING AND SCIENTIFIC PRESS, taken from a London paper. It is interesting to see to what extent

American Products

Find their way even to Hungary. The *Pester Lloyd* of February, 1873, says: "America seems to make herself more and more indispensable to us. After being provided with cotton, furs, meat and meat extract, bacon, lard, hides, barley, preserved fruit, she sends us now also cheese. The latter has the form of a mill stone, each weighing 60 pounds, similar in taste to our old, in former times known as Elbinger, cheese." Doubtless there are many other things yet exported from the United States not mentioned by the *Lloyd*, as coal oil, tools, etc., but certainly more would be imported, if the German and Austrian people were more acquainted with the different articles manufactured in the United States; and no better opportunity for this purpose will be offered than with the Vienna Exposition.

Crossing the sea from Hull, England, to Hamburg, the steamer "Sprite" was crowded with large agricultural machines, (from Lincoln, England,) destined to Austria. English steam-plows are used in Austria and Hungary and of late the progress in these countries in manufacturing and agricultural industry and commerce is quite striking. All this proves that there is a field for trading extending every year further east.

By the way, for the benefit of

Travelers to Vienna,

I would mention that, going from New York by way of England, the steamers of the Inman Line are not the most comfortable ones. Being used to the neatness and strict order on our Pacific steamers, one is quite surprised to find a marked difference in this respect on the "City of Antwerp" of the Inman Line to Liverpool. The first cabins are partly dark, the very annoying ship smell, strong. The cabins are not examined by the Captain at all during the whole trip; and table poor enough, if compared with the luxuries of the German steamers between

New York and Hamburg.

These steamers are built in England and run as fast as the best of the "White Star" Line. The cabins are very elegant, and accommodations cannot be better. Even the second-class cabins are preferable to the first of the Inman Line. With the passenger train from Hamburg, it takes about 30 hours to Vienna, (\$12.50) by way of Berlin; but it takes less time with the fast train (*Currier Zug*). The expenses in Vienna during the exhibition will not be so extravagant as generally represented. A person, being compelled to economize takes a private room, can manage with three dollars (coin) a day; in a hotel, with five dollars, but it is unnecessary to say that ten times more can be spent in less than 24 hours.

It is said that among the prominent personages who will be present at the exhibition are the Emperors of Russia and Germany, Queen Victoria, the Kings of Italy, of Belgium, of Denmark, Sweden, Greece, Wur-

temberg, Bavaria, Saxony, the Sultan, the Shah of Persia, Grand Duke of Baden, President Grant, Thiers and the Prince of Wales. The Shah will be accompanied by four princes and suite, probably the Mikado of Japan will be also present. Of inferior beings, but of noble race, from Tunis, Africa, 20 most exquisite selected Arabian horses will be shipped to the Exposition. It is also announced by telegraph that the steamer "Phase" sailed from Japan with Japanese articles.

It may be of interest to your readers to see a

Comparison of Space

Occupied by different countries in the World's Expositions of London, Paris and Vienna. Italy had in London 1,800, in Paris, 2,200, in Vienna, 4,788 square meters; Russia had in London, 1,400, in Paris, 2,232, in Vienna, 5,090; Germany had in London, 3,500, in Paris, 8,790, in Vienna, 21,136; the East had in London, 1,450, in Paris 2,547, in Vienna, 5,672. France occupied, in 1867, in Paris, 48,837 square meters; Austria-Hungary, occupied, in Vienna, in 1873, 65,212 square meters.

The finishing up of the Palace is progressing very rapidly. Seeing the plans and pictures of the building, one is surprised, nevertheless, with the grandeur of structure and space on entering. In my next I will send you some interesting views.

Vienna, February 28, 1873.

The Coinage Act.

The new Coinage Act went into operation April 1st. The Mint of the United States is established as a Bureau of the Treasury Department, embracing in its organization and having under its control all mints for the manufacture of coin and all assay offices for the stamping of bars. The chief officer of the Bureau is denominated the Director of the Mint, and is under the general direction of the Secretary of the Treasury. He is to hold his office for five years, unless removed by the President, upon reasons to be communicated by him to the Senate. Dr. Linderman will be appointed to this office, having been connected with the Mint, in responsible positions, for the last twenty years to the entire satisfaction of the Government.

The term Branch Mint is abolished, and the Mints at Philadelphia, San Francisco, Carson and Denver will be known as separate establishments. Those who are now Directors of Mints will hereafter bear the names of Superintendents. The offices of Treasurer of the Mints in Philadelphia, San Francisco and New Orleans are to be vacated, and the Assistant Treasurer at New York will cease to perform the duties of Treasurer at the Assay Office. The duties of Treasurers will devolve upon Superintendents, and Treasurers are to act only as Assistant Treasurers of the United States. The salary of the Assistant Treasurer at New York is not to be diminished by the vacation of his office as Treasurer of the Assay Office. The other Assay Offices are at Charlotte, North Carolina and Boise City, Idaho.

There is no change in the gold coinage, but in the silver coinage there is to be a new trade dollar. The two-cent piece is to be abolished, the minor coins being five, three, and one cent pieces. So much of the Sundry Civil Expenses Act of 1870, as provides that until after the completion and occupation of the Branch Mint building, in San Francisco, it shall be lawful to exchange at any Mint, or Branch Mint of the United States, unrefined or upstamped bullion, whenever, in the opinion of the Secretary of the Treasury, it can be done with advantage to the Government, is repealed.

COIN AND BULLION.—The receipts of coin and bullion at San Francisco for the quarter ending March 31st, through Wells, Fargo & Co's Express, were as follows:

	Silver Bullion.	Gold Bullion.	Coin.
January.....	\$295,261	\$892,477	\$917,137
February.....	323,375	535,325	621,152
March.....	332,677	653,915	865,979
Totals.....	\$951,313	\$2,081,717	\$2,404,328

Making a total of \$5,437,358. The sources whence this treasure was received are indicated as follows:

From northern and southern mines.....	\$4,041,663
From northern coast route.....	475,809
From southern coast route.....	190,158
From Mexico.....	729,728
Total.....	\$5,437,358

These figures show an apparent decreased production, as last year the receipts for the same time were \$9,053,202 and in 1871 were \$10,081,974.

ASBESTOS.—There are very extensive deposits of this important mineral within the limits of the United States, that found on the eastern slope of the Green Mountains and of the Adirondacks being of the best quality for fineness and tensile strength. The fiber of New York and Vermont asbestos varies in length from two to forty inches and resembles unbleached flax, when found near the surface, but when taken at a greater depth, it is pure white, and very strong and flexible. It is found also, in considerable quantities in the Tyrol, in Hungary, Corsica and Wales.

The Eureka Mill, Carson river, is running steadily and up to its full capacity. It is the largest mill in the country, and it takes a vast amount of ore to keep it running. As yet the cars on the narrow-gauge road that connects the mill with the Virginia and Truckee railroad are drawn by horses, but a small locomotive will probably be put on this summer.—*Enterprise*.

Leather Market Report.

[Reported for the Press by Dolliver & Bro.]

SAN FRANCISCO, Wednesday, April 2, 1873. The price of sole leather continues the same. French Calf Skins still have an upward tendency, with prospects of a further advance. Owing to the low price of currency East, tanners cannot ship. Leather is therefore low; but there have been some heavy shipments made to Japan, which in a measure help to compensate this.

PLACER MINES.—The *Silver State* says surface diggings are all the rage around Unionville now. Miners have been prospecting Cottonwood Cañon, and struck "two bits to the pan and the bed-rock pitching." George Simons and Joe Groves have quit four dollars a day in the silver mines and gone to Cottonwood, expecting to make better wages working gold mines on their own hook.

The Virginia and Truckee Railroad has put up the rates of freights on lumber as follows: From Carson to Gold Hill and Virginia, \$7 per 1,000 feet; from Reno to Gold Hill and Virginia, \$10 per 1,000 feet, or \$75, car-load rates.

ON TIME.—The *Register* states that the Idaho stages, which were hauled off for a week or two because of the epizootic, are now making regular time.

THE SMITHSONIAN INSTITUTION has received from the publishers, San Francisco, MINING AND SCIENTIFIC PRESS, VOL. XXIV, a gift for which it returns a grateful acknowledgment. JOSEPH HENRY, Sec'y T. S. I. Smithsonian Institution, W. C., Feb. 4, 1873.

NO LIFE INSURANCE COMPANY has a better record or more enhanced popular reputation than the CORNELL MUTUAL LIFE INSURANCE CO., of B. Roberts, 315 California Street, San Francisco, is general agent for this Coast. Send to him for circulars and information of this reliable, first-class company.

For the very Best Photographs go to BRADLEY & RULOFSON'S GALLERY, with an "Elevator," 423 Montgomery street, San Francisco. 26 1/2-3m-cowhp

CONTINENTAL LIFE INSURANCE CO., No. 302 Montgomery street, corner of Pine.

Try Dr. Ery's Diamond Catarrh Remedy. Only 50 Cents.

Says John to Nance, you look so bright, Your eyes they sparkle, like a star. Oh yes, says Nance, Dr. Ery's remedy Has cured that horrid, bad catarrh.

OUT OF THE FOO AT LAST.—Dr. Ery has discovered the only sure cure for Catarrh and Glands. One bottle gives immediate relief, and a few bottles effects a cure. All we ask is a trial. If your druggist don't have it, send to Dr. A. F. Ery & Co., 9 Post street, S. F. It only costs 50 cts. 14 1/2-3m

Spring Mountain Tunnel Company.—Principal place of business, No. 37 New Merchants' Exchange, Cal. office street, San Francisco, Cal. Location of works, Ely Mining District, Lincoln County, Nevada. Notice is hereby given, that at a meeting of the Board of Directors, held on the 15th day of March, 1873, an assessment of \$25 of twenty cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the Company, 37 New Merchants' Exchange, California street, San Francisco, Cal. Any stock upon which said assessment shall remain unpaid on the 15th day of April, 1873, will be subject and advertised for sale at public auction, and unless payment is made before, will be sold on the 5th day of May, 1873, at the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors, J. M. BUEFFINGTON, Secretary. Office, 37 New Merchants' Exchange, California street, San Francisco, California. m15

Mining and Other Companies.

On the 1st day of the month necessary to mail the present large edition of the M. & S. Press, we are obliged to go to press on Thursday evening—which is the very latest hour we can receive advertisements.

Angels Quartz Mining Company—Principal place of business, 408 California street, San Francisco. Location of works: Angels Mining District, Calaveras County, California.

Notice.—There are delinquent upon the following described stock, on account of assessment No. 1, levied March 4th, 1873, the several amounts set opposite the names of the respective shareholders as follows:

And in accordance with law, and an order of the Board of Directors, made on the eighth day of January, 1873, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the salesroom of Maurice Dore & Co., No. 327 Montgomery street, San Francisco, California, on the eighth day of March, 1873, at the hour of 12 o'clock, M., of such day, to pay delinquent assessments thereon, together with costs of advertising and expense of the sale.

CHAS. F. BALCOM, Secretary.
Office, 426 Montgomery street, San Francisco, California. 1522

Eagle Quicksilver Mining Company.—Location of works, Santa Barbara County, California.

Notice is hereby given, that at a meeting of the Board of Directors of said company, held on the 18th day of January, 1873, an assessment of fifty dollars (\$50) per share was levied upon the capital stock of said company, payable immediately in gold coin of the United States, to the Secretary at his office, Room 5, No. 327 Montgomery street, San Francisco, California. Any shares upon which said assessment shall remain unpaid on Wednesday, March 19th, 1873, shall be deemed delinquent, and he who advertised on Saturday, March 22nd, 1873, for sale at public auction, and unless payment shall be made before, will be sold on Monday, the 24th day of March, 1873, to pay the delinquent assessment, together with costs of advertising and expense of the sale.

WM. H. WATSON, Secretary.
Office, Room 5 and 6, No. 327 Montgomery street, San Francisco, Cal. 1525

Frear Stone Company of California.—Location of principal place of business and works, City and County of San Francisco, State of California.

Notice is hereby given, that at a meeting of the Directors, held on the first day of April, 1873, an assessment (No. 5) of two dollars per share was levied upon the capital stock of the corporation, payable immediately in gold coin of the United States, to the Secretary, at the office of the company, No. 414 California street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 30th day of May, 1873, will be delinquent, and for sale at public auction, and unless payment is made before, will be sold on Monday, the 26th day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

R. WEGENER, Secretary.
Office, 414 California street, San Francisco, Cal.

Gold Run Mining Company.—Principal place of business, San Francisco, California. Location of

works, Nevada County, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 15th day of March, 1873, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in gold coin of the United States, to the Secretary, at the office of the company, No. 414 California street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 30th day of May, 1873, will be delinquent, and for sale at public auction, and unless payment is made before, will be sold on Monday, the 26th day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

O. C. PALMER, Secretary.
Office, Cor. Market and Spear Streets, San Francisco, California. m22

Hardy Coal Mining Company—Principal

place of business, San Francisco, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 26th day of March, 1873, an assessment of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, Room 5, No. 335 Montgomery street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the first day of May, 1873, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 24th day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

J. A. O. HARDY, Secretary pro tem.
Office, Room 5, No. 335 Montgomery street, San Francisco, Cal. 1m23-4t.

Keystone No. One and Two Gold and Silver Mining Company.

Principal place of business, San Francisco, California. Location of works, Wailapa Mining District, Mohave County, Territory of Arizona. Notice is hereby given, that at a meeting of the Board of Directors, held on the 10th day of March, 1873, an assessment of twenty-five (25) cents per share was levied upon the capital stock of the corporation, payable immediately in gold coin of the United States, to the Secretary, at the office of the company, No. 507 Montgomery street, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the 15th day of April, 1873, will be delinquent, and for sale at public auction, and unless payment is made before, will be sold on the 15th (5th) day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

T. E. JEWELL, Secretary.
Office, No. 507 Montgomery street, San Francisco, Cal.

Lady Franklin Gold and Silver Mining

Company.—Location of works, Silver Mountain Mining District, Alpine County, State of California. Principal place of business, San Francisco, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment No. 1, levied on the eighth day of February, 1873, the several amounts set opposite the names of the respective shareholders as follows:

IMPORTANT TO

Quartz Mining Companies.

IMPROVED PATENTED

Hardened Cast Steel Shoes & Dies.

The undersigned are prepared, at short notice, to furnish IMPROVED PATENTED HARDENED CAST STEEL SHOES AND DIES, for Quartz Mills of every pattern. This improvement supplies a want long needed by persons engaged in Mining enterprises. They are more economical and cheaper than cast iron shoes, as they wear from four to six times as long, and crush a greater quantity, as they retain their full diameter, never chipping from the edges. This, with the time saved in replacing worn and broken iron shoes and Dies, and the great saving of freight to remote mills and mines, makes a vast difference in the cost of reduction of ores.

WE ALSO FURNISH

Cast Steel Tappets, Cams, Picks and Hammers,

Which possess the same advantage of Economy and Durability, and deserve the special attention of Miners and others engaged in quartz crushing.

The Superior Strength of these steel castings—the fact that they can be forged and welded as easily as bar steel—their cheapness and great accuracy, as compared with forged iron—cannot fail to make them desirable for many purposes, where forged iron and steel have heretofore been used. Among such articles we mention:

ROLLING MILL CASTINGS.

Bevel and Spur Wheels, Guides, Spindles, Dies, etc. AGRICULTURAL CASTINGS. Reaper Guards, Plow Shares, Mold Boards, Plow Jointers, etc.

Anvils, Sledges, Vices, Masons' Hammers, Blacksmith Hammers, Mattocks, R. R. Frogs, etc. And other articles requiring solidity and great strength.

DONKEY ENGINES FOR HOISTING,

Mining Machinery, Etc.

Persons giving orders will send diagrams and measurements of Shoes and Dies, etc., as above.

J. G. KITTREDGE & CO.,

No. 515 California street, San Francisco.
12v23-1f

Scaling and Foaming Prevented and Fuel Saved.

Enquirers are respectfully informed that

WARSON'S AERO STEAM SYSTEM

Has been well tested, during three years, in England. Besides the above advantages, it greatly prolongs the life of Boilers, Tubes and Fire-boxes.

It is a cheap contrivance, and easily applied to any engine.

Illustrated Circulars, showing the appliance and describing its advantages, are sent to all applicants.

All who are troubled with Scale and Foaming may rely on this system of prevention—also on saving at least 20 per cent. of fuel.

RICHARDS for States and for individuals will be sold on liberal terms.

J. L. SANFORD,

General Agent for United States,

420 Montgomery street, San Francisco,
And Box 369, P. O.

Information Required to Give an Estimate of Warson's Apparatus:

- 1.—Diameter of Cylinder.
- 2.—Length of Stroke.
- 3.—Number and Length of Boilers—Tubes or Flues.
- 4.—Distance of Boilers from Engine.
- 5.—Can Pump Piston be attached to Cross-head of Engine?

It can, however, be driven by any of the usual appliances that work the Water-feed Pump.

These items will enable me to give a near estimate of the cost.

J. L. SANFORD, General Agent.

Notice is hereby given, that the copartnership heretofore existing between A. J. Severance, Charles W. Randall and J. Gus. Burt, under the firm name of "Severance, Holt & Co.," is this day dissolved by mutual consent. A. J. Severance, having purchased all the interest of his late partners, will continue the business of manufacturing and selling Diamond Drills as before, under the style of A. J. Severance & Co.

Dated San Francisco, Nov. 24, 1871.
Office, 315 California street. A. J. SEVERANCE,
CHAS. W. RANDALL,
J. GUS. BURT.

and Maker of Models for Inventors. All kinds of Dies Stamps and Punches made. Also, all kinds of Small Gear Cut.

Repairing done on very Reasonable Terms and in the best manner. No. 32 Fremont street, S. F. 19v22-3m

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 125 First street, S. F. 24v23tf

PACIFIC LAMP MANUFACTORY.

EMIL BOESCH,

Patentee and Manufacturer of

The California Powder Works

No. 314 CALIFORNIA STREET,
SAN FRANCISCO.

Manufacturers and have constantly on hand

SPORTING, MINING, AND BLASTING POWDER,

OF SUPERIOR QUALITY, FRESH FROM THE MILLS. It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market.

We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

We also call attention to our

HERCULES POWDER.

Which combines all the force of other strong explosive powder in use, and the lifting force of the BEST BLASTING powder, thus making it vastly superior to any other compound now in use.

A circular containing a full description of this Powder can be obtained on application to our Office.

BURLEIGH ROCK DRILLS

— AND —

Air Compressors.

The Burleigh Rock Drills, which have stood the test of five years' constant use at the Hoosac Tunnel, and which are now in use in nearly every State in the Union, as well as in Europe and South America, are unequalled in efficiency and economy by any other Drilling Machine. They are of various sizes, and equally well adapted to Tunneling, Shafting, Open Cut or Quarrying, and will drill six to ten inches per minute in granite. They are driven by steam above ground. The Burleigh Air Compressor is the best engine yet devised for furnishing the "air motor" for the many purposes to which it is now being used. They are to be used on the St. Gothard Tunnel, Switzerland; Tunnel 13 miles long. We refer to the following gentlemen and works:

BROWN'S PATENT LAMP.

One of these Lamps, when placed at a distance of 200 feet from the bank, will light up a bank surface 250 feet in length and 150 feet high, and to a much better advantage than any other light heretofore tried, and at an expense not to exceed five cents per hour. Lamps furnished at short notice.

Letter of Recommendation.

Mr. O. B. Brown—Sir: Your Patent Lamp for lighting hydraulic mines, which you sold to me in December last, has given entire satisfaction, and far exceeds my expectations, and I think it the best and cheapest light ever used to light mining claims by night, and am satisfied that I have saved three hundred dollars by the use of it in the last mining season over pitch or any other light of the same brilliancy; and I will also say that if it could not get another lamp, five hundred dollars would not buy it. Yours, W. D. APLIN.

Little York, Nov. 5, 1872.

For further particulars, address,

HALLIDIE'S
Patent Endless Wire Ropeway.
Covered by Numerous U. S. Patents.

IMPORTANT TO
Mining Companies, Civil Engineers, Contractors, Etc.

This system of transporting material, such as Ores, from the mine to the mill, Earths for embankments, Rock from quarries, etc., by means of steel wire rope, has been well tested and found more economical, advantageous and reliable than any other method of transportation; and to the annexed certificates in connection therewith I beg to call the attention of those interested:

EUREKA, Nevada, July 10, 1872.
T. M. MARTIN My dear sir: On your leaving for San Francisco, it gives me great pleasure to hand you my written acceptance of the HALLIDIE TRAMWAY put up by you upon our mine in Freilburg.

It is a perfect success, discharging ten tons of ore per hour with two men's labor. It is perfectly simple in construction, and, as far as I can judge, there is nothing about it to ever get out of order—nothing to wear out. While others require but about two thousand five hundred feet of wire rope, I can see no reason why the line could not be extended almost indefinitely with equally happy results. Again, the carrying capacity might be doubled or quadrupled if desired. After several weeks trial upon our mine, the unanimous verdict of all who have seen it is a complete, unquestioned success. If this can be of any service to you, use it in any way you think proper. Very respectfully, C. C. GOODWIN.

EMMA HILL CONSOLIDATED MINING CO., Little Cottonwood, Utah.
Superintendent's Office, Sept. 28, 1872.
T. M. MARTIN, Esq., Ropeway, The Ropeway constructed by you (HALLIDIE'S PATENT) for the Emma Hill Consolidated Mining Company, has been built in a most substantial and workmanlike manner, and is at this time in splendid working condition. I most cheerfully accept the work for the Company, and recommend it to others wishing a sure and speedy transit for ores over places impracticable for wagon roads, etc. Respectfully,
L. W. COLBATH, Superintendent.

"The Vallejo works smoothly with the elevated wire tramway, which carries its load of ore as quietly and easily as if there was no winter or snow in the world. Whatever the objections to wire tramways may be on account of their cost, I have seen nothing yet that even approaches them in the facilities they afford for moving ore at all seasons of the year."—Correspondent Utah Mining Journal, Aliso, Jan. 8, 1873.

The Vallejo Ropeway.
The Vallejo Tunnel Company's Tramway in Little Cottonwood, built on the HALLIDIE PATENTED PLAN, is a complete success. It is between 2,300 and 2,400 feet in length, and is supported by thirteen stations. The fall to this distance is about 600 feet, and the wire rope, which is three-fourths of an inch in diameter, will easily and easily deliver one hundred tons in six hours. The machinery is automatic, loading and unloading the sacks or buckets. About one ton and a half can be sent down at one time. The stations are about two hundred feet apart, and the entire apparatus is strong and safe. As the wire rope is elevated about forty feet above the surface of the hill, the Tramway can be worked all winter long, without the slightest trouble.—Utah Mining Journal, Salt Lake, Sept. 22, 1872.
Mining Companies and others desiring to negotiate for the erection of this system of Ropeway, can communicate with me personally, or through Postoffice Box 904.

A. S. HALLIDIE, Patentee,
112 and 114 California Street, SAN FRANCISCO.

WIRE ROPE
For hoisting from mines, transmitting power, ship rigging, etc., of all kinds and sizes, on hand and made to order.
Wire of all kinds and descriptions, furnished at lowest rates.
A. S. HALLIDIE, 112 and 114 California St.

Number 15.

Fisk's Self-Acting Wagon Brake.

We should consider an invention praiseworthy at least which has for its object the simple amelioration of the labors which we impose upon our beasts of burden and of draught, but when that invention also possesses advantages of importance and utility outside of a mere saving of animal strength it then acquires an additional value, which should recommend it to public favor. In all hilly and mountainous countries the most exhausting task of beasts of draught is to hold back upon the wagon while descending hills; this is especially fatiguing and laborious for the reason that our common road vehicles are not constructed with a view to down hill work, but are made to accommodate a direct pull. Farm wagons in the mountainous portions of the country do not last as long as those employed on level roads, for the reason that a loaded wagon is subjected to such severe strains by the unsteady hold back of the team, when no competent brake is used. The ordinary hand brake serves to hold the wagon when properly applied, but it is quite inconvenient and it requires a very nice adjustment in order to properly gauge the breaking force to the load in the wagon and steepness of the declivity.

Mr. Oliver Fisk, of Centerville, Mariposa county, in this State, has invented and secured letters patent, through the SCIENTIFIC PRESS Patent Agency, both in the United States and Canada, for a self-acting wagon brake, an illustration of which is herewith given. By his arrangement the combined action of the gravity of the loaded wagon and the first hold back of the horses upon commencing the descent of a declivity applies the brake automatically, according to the requirements in each case, and looks the brake in position against the wheels, so that they will apply the necessary friction during the entire descent without requiring any further holding back from the team. When the wagon reaches the bottom of the hill the first pull of the team upon the double-trees frees the brakes and the wagon again moves freely.

This is accomplished by means of a pawl and ratchet, situated just behind the double-trees. The pawl is so connected that when the wagon begins to move forward by the impulse of gravity, the pawl will be pressed back, and through the levers, c and d, and their connecting arms, the brake bars are forced against the wheels. The pawl falls into the teeth of the rack and thus holds the brakes against the wheels until the bottom of the hill is reached, or until the first pull of the horses takes place. By means of a bell crank lever this pull upon the double-trees throws the pawl up out of the rack, and the action upon the levers and brake-bars is such as to again move the brakes away from the wheels.

For further information address Mr. Oliver Fisk, Centerville, Mariposa, county, Cal.

LARGE FISH BREEDING ENTERPRISE.—Claus Spreckle proposes to drain the chain of lakelets and ponds on his ranch, to the west of the Watsonville road, Santa Cruz county, and excavate all the mud and sediment, and then run a feeder or ditch to the small stream heading up near Buzzard Lagoon, so as to form artificial fish-ponds, for the raising of choice fish for table use. The ponds, when ready, will be stocked with eastern trout, black bass, pike and pickerel.

Mining vs. Speculation.

In one of our late issues, allusion was made to the manner in which some few of our prominent mining speculators manipulated the stock market, so as to put up or down the price of shares at will, totally irrespective of the value of the particular property in question, and how every such fluctuation in price involved pecuniary loss to all outside speculators.

During the past fortnight a few of the old crowd of operators have been strenuously endeavoring, by resorting to their usual trick, to inflate the price of certain Comstock mines. "Reliable information" regarding imaginary strikes, was being telegraphed by superintendents and others about the mines to their friends(?) in this city; the contrivances

ing as in every other business, or else such moles as the Emma, Richmond, or Geddes and Bertraud, would prove no more remunerative to their owners than the Overman or Hale & Norcross; which latter, by the bye, although supposed to be one of the best managed mines on the Comstock, has not returned to the stockholders more than one quarter of the gross yield in dividends—only three-fourths of the total yield for expenses.

However, it is highly probable that, on the decline of stock gambling, legitimate mining will resume the way; and when this happy consummation shall have been attained, the yield of precious metals from the Pacific States, will be such as to astonish the world.

Academy of Sciences.

The regular meeting of the Academy of Sciences was held on Monday evening, and Samuel O. Gray, H. H. Haight and Samuel F. Reynolds

FISK'S SELF-ACTING WAGON BRAKE.

of a few of those seedy looking individuals who hang around the corners, and are known as curbstone brokers, brightened up at the prospect of the little commissions that would fall to their share for helping, in their small way, some of the big fish in their dirty work. But these stale old games have been played once too often, and the mining sharps find to their great disgust, that no one who has any money to lose puts the slightest confidence in their plausible stories, and that no one with any character to lose will countenance any of their swindles.

This is just as it should be. The business men of this city who have always been ready and willing to advance money for any legitimate mining enterprise, appear to have formed a pretty correct estimate of the character of the men composing the mining rings of California street, and now carefully shun them and the mines they control. Let the Hale & Norcross, Savage and Virginia Consolidated crowd work their claims at a profit or a loss; let them declare dividends or levy assessments just as it suits them; let the Jones-Hayward and bank parties do the same with their mines, for the future it will make but little difference to the community at large, who are no longer willing to be duped.

Capitalists who feel disposed to invest some of their surplus in mines will know that there is an inexhaustible field for the investment of their money in the many well known rich quartz veins of California, and in the silver lodes of Central Nevada, Utah and Arizona. In such districts as Tintic, Belmont, Columbus, Hualapai and others, there are many mines now unworked, which, if managed with prudence and economy, as some of the English companies on this coast are, would prove most remunerative to the owners. But wanton extravagance must be avoided in min-

were duly elected members. Among the donations to the cabinets were they following:

Crustaceans, presented by Professor Davidson; were caught at night near Cape St. Lucas; water was perfectly white from phosphorescence. Two of them will light up a bucketful of water.

Dr. Gibbons presented on the part of Dr. Cleveland, a portion of a deer's head, showing an arrested development of the antlers in consequence of injury to the testes.

Skull of lagenorhynchus albirostratus, caught by Capt. Martin, on a voyage from Tahiti to San Francisco. Presented by proprietors of the *Alta*.

Barnacles from green turtle, Mazatlan; small ones from Cape St. Lucas; larger ones from stomach of a bonita (fish), caught off Lower California.

Large snake from San José de Cabo. Presented by Professor Davidson.

Large specimens of scorpions, lizards, etc., from Mr. Gillespie, United States Consular Agent at San José de Cabo.

Nine large and handsomely illustrated volumes of Kingsborough's Mexican Antiquities and Dupaix' Monuments were presented by a new member, Mr. Geo. C. Hickox; total cost of the set \$1,500.

Death of Prof. Torrey.

Mr. Dall read a paper on the life and services of John Torrey, Professor of Botany and Chemistry, who died on the 10th of March, aged 77 years. Dr. Gibbons followed in a brief address, in which he alluded to the two visits made by Prof. Torrey to the Pacific Coast.

Miscellaneous.

Prof. Davidson read a paper containing the result of his inquiries as to the exact geographical position of the observations taken of the transit of Venus at San José del Cabo, in Southern California, in 1868 to which full reference is made in another column.

F. Gutzkow described a new process for the

extraction of boracic acid, which will be found in another column. A letter was read, written by Harry Edwards, stating that Lewis Frazer, an old man who has performed great service in the fields of science, is now destitute and suffering in British Columbia, and suggesting that a contribution be taken in aid of his family.

After the adjournment a number of members added their names to that of Mr. Edwards on the paper. Mr. Fraser is one of the survivors of the Nile expedition, and is the author of several scientific works.

The Transit of Venus in 1769.

In the year 1769, the French Government sent an astronomical party, under charge of M. Chappe, to a point known as San José del Cabo, in the southern extremity of Lower California, to observe the transit of Venus which occurred that year. The observations of this party are considered of great value, but unfortunately the geographical position of the station was not well determined, on account of the sudden death of the principal of the expedition, which occurred soon after the transit and before any proper detailed plan of the locality had been made. Efforts have since been made to discover the precise location but without avail, until quite recently, when that part of the Coast was visited by Professor Davidson of the Coast Survey, under the especial authority of the Superintendent of the Coast Survey.

While there, Professor D., succeeded in finding the spot, and in determining its latitude and longitude.

The foundations upon which the instruments were placed had been covered up many years ago; but Professor D. thinks he has located them within an area of 20 feet square, or a possible error of 10 feet of latitude and longitude—a pretty close approximation, truly.

The latitude was carefully determined by the usual observations, made by Mr. Eimbeck, and also the longitude by means of twenty-four chronometers taken from San Diego and back—the longitude of San Diego being well determined by telegraphic connection with Greenwich, via San Francisco and Cambridge. These results will make available the excellent observations made by M. Chappe of the transit of Venus of 1769, although 104 years have elapsed since they were made.

These facts have a special interest in view of the coming transits of Venus, in 1874 and 1882, to observe which, astronomers all over the world are making preparations of unusual completeness.

The chief importance connected with the transits of Venus is the determination of the sun's parallax—or in other terms the distance of the earth from the sun. From the observations of the transit in 1769, there was at first discovered a parallax of 8.576 seconds of arc—corresponding to a distance of 95,311,000 miles. Subsequent discussions of these observations have increased the parallax to about 8.9 seconds—corresponding to a distance of about 91,800,000 miles; a very important margin of possible error. It is hoped that the transit of 1874 will enable astronomers to arrive at more definite and reliable data.

We have condensed the above from a paper read by Prof. Davidson before the Academy of Sciences, at their meeting on Monday evening last.

PATENT OFFICE RECEIPTS FOR MARCH.—The total amount of cash received by the Patent Office, for patents and otherwise, during March, was \$69,790. The amount exceeds that of any one month since the creation of the Office,

CORRESPONDENCE.

Nevada County—Letter From "Old Block."

(Written for the MINING AND SCIENTIFIC PRESS.)

Our town still lives. Amid the revulsion of the mining stock market we move calmly along, untouched by the blighting storm of stock gouging, depending upon the merits of our mine and not upon assessments to keep our mines in operation. There is not a single developed quartz mine in the township but what is paying more than expenses, and some of them are paying very large dividends.

The Idaho, for instance, yields monthly about \$60,000; the Eureka from \$40,000 to \$50,000; the Empire and North Star from \$10,000 to \$15,000, and \$20,000, while some of the smaller and undeveloped mines are paying equally as well in proportion to the capital invested and the size of the machinery used.

The Green Mountain, one of the Osborne Hill mines, with only five stamps, and a small vein, has taken out in eighteen days over \$6,000. The Dairy Hill in a crushing of about ten days yielded over \$6,000. The State ledge (Pinsou & Brown), is yielding like the others. The Dartmouth, under the supervision of Capt. John Miller, is beginning to reward his perseverance, paying something over expenses. This last is a gravel mine situated at the base of Alta Hill. Capt. Miller was singularly unfortunate in the commencement. He built a fine mill for his company and had just got it completed when some malignant fiend set it on fire, and it was totally consumed. Within sixty days a new mill was built and ready for operation, an evidence of his activity, perseverance and grit, and is now doing fine work on the rich gravel, supposed to have been the bed of an ancient river. There is every indication that he will ere long get his money back with miner's interest.

Grass Valley is decidedly in a prosperous condition. We are shipping about \$250,000 in bullion monthly, and we have a capacity, if it were improved, of taking out over a million per month. I am sincere in the belief that Nevada county is one of the richest gold districts in the world. A residence of twenty years here has given me opportunities of gaining information with regard to the character of the golden belt, and from statistics which I have been trying to gather I am satisfied that the total amount of gold taken from the county since its settlement will not fall short of one hundred and fifty millions of dollars; and we are only upon the threshold of the golden deposit. There are many valuable mines which have been abundantly proved good, that are laying idle, simply for want of capital to reopen and work them with the new and improved appliances of mining. Even Grass Valley, within a radius of about four miles by seven, has added to the circulating medium of the world over forty-five millions of dollars.

We have been a little amused with Professor Carr's lecture, given some time since in Oakland, in which he endeavors to depreciate the mining interests in California. He is evidently not fully posted on the subject when he says that there are 50,000 miners at work in our mines, and that every dollar extracted costs a dollar and a half. I guess he has been bit by investing in a poor or badly-managed mine. Let him take a trip through Nevada County and see what has been done within twenty years; the towns built up; the thousands of good homes made; the taxable property instituted; the thrifty mercantile stores opened and various branches of business; the expensive water ditches bringing water from mountain snows; the public buildings erected and fine farms opened—all from the produce of these very mines which he holds in such low estimation, and be must see the "error of his ways" and "repent before it is too late." While we would uphold the mining interest for exactly what it is—one of the greatest industries of the State—we would not depreciate the other great industry—agriculture. It is indeed great, and deserves encouragement, and we hope to see it prosperous and remunerative; but we will believe that the mining interest is really one of the greatest, and deserving encouragement. More anon. Old Block.

Grass Valley, March 31, 1873.

The Whelpley & Storer Pulverizer.

A correspondent of the *Lessen Advocate* writes to that paper as follows concerning the pulverizer of the Whelpley & Storer pattern which has just been put in operation at Hayden Hill:

A few days since, in company with several ladies and gentlemen of this place we went, at the invitation of J. C. Layton of San Francisco, to see the starting of one of the above mills, which has been put up for the Old Providence Mill and Mining Co. at Hayden Hill, under the supervision of the above named gentleman; said mills being used for the crushing and sampling of ores, pulverizing foundry facings, salt, paints, cements, or any other material, to any degree of fineness.

The building in which it is erected is 20 by 60 feet. In the rear at an elevation of 22 feet the crusher or breaker is fixed. This is an iron cylinder or tub, the sides of which are thick, wrought iron plates, perforated with holes three-fourths of an inch in diameter. The

cover of the cylinder is made of two plates of cast-iron, in one of which is an opening through which the rock passes to be crushed. The bottom of the cylinder is a strong cast iron plate on which are placed several blocks of iron faced with steel, and is attached to an upright shaft which revolves at the rate of 1,400 revolutions per minute. This whole machine is surrounded by a close chamber for the collection of the crushed material, and is calculated to break 10 tons of hard rock per hour, one-half of which will pass through a No. 40 sieve, and the remaining portion to be about the size of a bean.

The pulverizer acts directly under the chamber or hop of the crusher and is constructed solely for the pulverization to dust of the rock coming from the crusher; this machine has the appearance of a large Saratoga trunk, and on lifting the iron cover, is a series of paddle wheels revolving on the inside, and which reduce the gravel to dust—the paddles, when in motion, producing whirling or vortices of air, which put the particles of rock in rapid revolution and is supposed to move at the rate of two miles a minute, and it is by the friction of the particles, one against the other, that the dust is produced, and the quality of this work determined by the velocity of the paddles. Connected with this machine is a fan-blower, through which the dust is drawn by exhaustion as fast as produced, and collected into a close chamber; pressure of air upon the interior of the dust room, and consequent back pressure upon the column issuing from the pulverizer, is prevented by a pipe leading from the extremity of the room back to an opening in the pulverizer, close to its feed hopper, thereby inducing a constant circulation of air.

Under the dust chamber of the pulverizer is an iron barrel into which is placed 800 pounds of dry dust and 65 pounds of quicksilver, and is run at the rate of 25 revolutions per minute. This is allowed to remain in the barrel for the purpose of amalgamating three-fourths of an hour; it is then drawn off into an iron bucket and diluted with water, where it still further remains (one hour); after which it is run over silver plates to the tail-race. The rock is first dried and run through each of the machines and barrel run; this being found to be the best process for ore in which so much fine, light gold is contained. The advantages claimed over the common stamp are better work and a much larger amount at the same time, less wear and tear, less cost in price of machine, freight, and erection, and above all, better satisfaction in results. Mr. Layton informed us he had recently put up one of these machines at Angel's Camp, and which the agent had since visited and reported it as doing well and given much better satisfaction to the company for whom it was erected, than the mill formerly used. The starting up of the Providence Company's mill was a success; it moved with the greatest ease, without a hitch, and as quietly as if it had been at work for months. It was admired by the lookers-on, and Mr. Layton was heartily congratulated on the success with which the start went off.

Letter from Dutch Flat.

Grey's Hill.

Grey's Hill, on the southwestern slope of which the business portion of "the Flat" is built, comprises the most noted gravel bed in this mining district. It has been the theater of active hydraulic operations since the hydraulic era began, but has declined in importance until but four small claims, located near the western end, are now running. As you ramble over it, a constant view of desolate hydraulic fields is unrolled before you, and, if the day is a sunny one, you are almost blinded by the white glare of the rocks, cuts and junctions that, with decaying trestle works, crushing flumes, sinking engines and blacksmith shops, make up the deserted scene. In mining parlance, the hill is "scalped," worked out on the old level, the lower strata and bed-rock remaining to be developed. The hill contains three hundred and fifty acres, rim included; but a fair estimate of the remaining channel deposit would be two hundred and twenty acres, averaging in depth one hundred and twenty-five feet. This is a blue gravel deposit, and supposed to be a continuation of the great blue lead of the State. It has been imperfectly tested at various points by claim owners, through shafts and bed-rock tunnels, generally showing colors, and in a few instances rare prospects; but no attempt has ever been made to hydraulic it on a bed-rock level. The reader can tell as well, or nearly as well, what the lower strata would pay under hydraulic treatment as the claim owners of Dutch Flat. It is one of the thousand local mysteries of the mines that capital and skill must unravel.

Dutch Flat Blue Gravel Mining Company.

Near the center of the hill is a mine of note styled "The Dutch Flat Blue Gravel Mine," containing forty-five acres, owned by a San Francisco company. The mine was purchased by a company in 1871, and in November of the same year, preparations for hydraulic mining a second stage was commenced. A hundred men were sometimes employed, \$18,000 worth of pipe laid down, 1,000 feet of flume constructed, 1,000 kgs of powder exploded, 2,000 inches of water (afterward reduced to 1,200 inches) turned on, a run of fifty days accomplished, and the mine closed down—a mining miscarriage, re-

sulting, according to popular verdict, from the level on which the enterprise embarked. The officers of the company are, or were, L. A. Booth, President; George D. Roberts, Vice-President; T. D. Bagley, Secretary; E. B. Dorsey, Superintendent.

The Dutch Flat Claims.

Adjoining the Blue Gravel mine on the east lies the Dutch Flat claim, containing forty acres, owned by shareholders scattered from White Pine to San Francisco. In their hydraulic days, these were the most celebrated claims in this part of the county, furnishing employment to a large body of workmen, and paying handsome dividends to stockholders for the period of eight years. They are now noteworthy as having been very recently handed to the Dutch Flat Blue Gravel Company. It is currently reported that, having secured these adjoining acres, the Dutch Flat Blue Gravel Company purpose speedily reopening on a level that will practically demonstrate what its mines are worth.

Freighting a Ship.

It is the opinion of several prominent Dutch Flat mine owners that the Blue Gravel and Dutch Flat mines combined contain money enough to "freight a ship." The estimate is perhaps a liberal one, but undoubtedly they contain an immense amount of the precious metal; though it is easy to comprehend that the success attendant upon hydraulic mining must depend on the manner in which the mines shall be opened and handled; for a ship may be sunk, as well as freighted, by the management of a mine.

The balance of the hill is made up by small groups of claims, containing three to ten acres to the group, owned mostly by workmen, and is of small practical importance in its multiplicity of ownership, but presents a fine chance for capital to create an extensive mine.

Price of Mines.

The Blue Gravel and Dutch Flat mines are reputed to have been purchased and loaded for the sum of one hundred thousand dollars each. The public ear is greatly saluted with round sums in regard to mining transactions, and the cautious listener becomes accustomed to throw off at least twenty to thirty per cent. of the floating statement. The smaller mines claim relative value with the larger, but fluctuate in price as new enterprises and fresh capital are sent in the field.

Hydraulic Claims.

Approaching the lower end of the hill you arrive at the "Deep Shaft" claims, delivering six hundred and fifty inches of water through one of Hoskies' 6-inch nozzles, under a pressure of two hundred and fifty feet, supplied by pipe fourteen inches in diameter. They belong to the Cedar Creek group, and are locally distinguished as having been E. L. Bradley's pet claims before his transfer of property to the London company. They were always obstinate claims to work, made up of adamantine banks, and therefore seemed to possess a peculiar charm for their former patron—a man who never turned aside for obstacles, but who persistently battered down every obstruction on his pathway, from a life of daily labor in the mines to the realization of a splendid fortune and a valley home. The new management has been fighting these banks a few rounds, and has concluded to throw up the sponge. The claims are closing down, their slight top stone is being washed away, their huge nozzle now scorching piping toward the skies, as if calling on Newton to witness its heroic closing struggle. Under the direction of the London company, the Blue Lead has lately been pretty well prospected in these claims, through a shaft with radiating tunnels. The work extended through a period of six months, and was recently closed down. A thousand of the *Union's* readers are working in the Blue Lead in this State, and keeping them in view, the writer will not assume to tell what the lead "averages to the pan for the last four feet." In the late work at this point prospects were obtained that, in some instances, almost warranted drift mining.

The Enterpriss Claims.

These claims adjoin the Deep Shaft on the north, and are Cedar Creek property. They are running day and night, employing five hundred inches of water through one of Hoskies' six-inch nozzles, supplied by main pipe fourteen and eleven inches in diameter, under a pressure of one hundred and fifty feet. These claims were opened this season, and bid fair to be exhausted by this season's close. They are located on the rim, and are washing to the bed rock. The banks are low, and high spurs of bed-rock impede the progress of their flumes. They are completing their second run of the season.

Badger Claims.

To the southwest of the Enterpriss, lie the Badger claims, owned by Grey & Co. They run day and night employ three hundred and fifty inches of water through one of Hoskies' four-inch nozzles, fed by twelve-inch pipe, under uncertain pressure. The bank is made up by a low front wall of gravel plastered on to a high back wall of clay—the clay from this point in northeasterly and southwesterly directions appearing to usurp the slope or level occupied by the hydraulic gravel at the upper end of the hill. The gravel yields slowly before the pipe; the claims have many difficulties to contend with, and have not made a thorough clean up this season.

The Sailor Claims.

Last claims of all, to the northwest of the Badger and owned by Simons. They consist

of a small island of gravel sitting in a sea of clay, and contain four to five runs. They work day and night, using 250 inches of water through two small pipes, and sluice their tailings through a flume 2½ feet in width.

The Flag of St. George.

Our English consuls seem determined to post themselves in regard to the profits of hydraulic mining in California, apparently having adopted the plan of buying up and mining a few thousand acres of our gravel rangers, by way of ascertaining what the whole may be worth, "you know." Last week the Little York Ditch and Mining Company's interests, consisting of 60 miles of ditches, 100 acres of mining ground, saw-mill, teams, etc., were transferred to a London company. The style of the company is: Little York Gold Washing and Water Co., Ltd; headquarters, London. Ball, President; Henry May, Secretary. Thus the Cross of St. George has been successively planted (at Bunker Hill prices) in the three contiguous towns of Dutch Flat, Little York and You Bet.—*Cor. Sac. Union.*

What the State Geological Survey has Accomplished in Indiana.

Prof. E. T. Cox, State Geologist of Indiana, in his annual report of the Geological Survey of that State, just published, says:

At the present rate of progress of mining in Indiana, a few more years will develop an endless chain of mines over the entire area of the coal field of Warren county on the north, to the Ohio on the south, with a belt of blast furnaces girdling the zone of the block of iron smelting coal.

The old furnaces are all in blast and making good yields of iron. Arrangements are being made to build a new furnace, to be placed beside the Brazier furnace, which is to be blown by the machinery originally designed to run two stacks. Another to be built at Terra Haute by the Virgo Iron Company, and one has already been built at Shoals, in Martin county, which will use principally native ore, referred to in my report of 1870. This ore occurs in great abundance in Martin county, and the semi-black coal found in Sampson Hill, a short distance south of Shoals, will supply it with fuel.

It is also highly satisfactory to know that by making known the extent and economical value of the minerals, the survey has had the effect to stimulate mining and manufacturing interests wherever it has been carried. I might further illustrate this by citing the increased activity in mining operations which it has brought about in Davies county. At Washington, in this county, mines have been in operation since the opening of the Ohio and Mississippi Railroad in 1856, and the business has grown to fair proportions, but I think it may be said, without fear of exaggeration, that coal mining has received an impetus, and operations in that time have increased with a rapidity heretofore unknown. Lands which were rated at fifty and one hundred dollars per acre have advanced to two and three hundred dollars per acre, and capital from various parts of the country has been turned to this county for profitable investment. Instead of having their mining operations restricted to one seam—the Washington coal—the survey has pointed out the existence of no less than eight distinct seams, five of which are of a workable thickness.

AGRICULTURE AND MINING COMBINED.—The vineyard now being planted by the Natoma Water and Mining Company, at Alder Creek, near Folsom, Sacramento county, is to contain 150 acres, and will contain over 70,000 vines—all foreign varieties, principally White Muscat and Flame Tokay. The vines were all rooted at Taylor's Nursery, last season. They are being planted at the rate of 7,000 per day, eight feet apart. Between every twenty rows a roadway is left. The vineyard is alongside the Sacramento Valley Railroad, and extends about a mile in length, and is so situated that it can all be irrigated from a large reservoir at the upper end. The company have also planted out 1,600 pear trees of choice varieties, and next season intend to plant 16,000 plum trees, on a tract of land now being prepared near Willow creek.

KLAMATH COUNTY MINES.—Mr. James Beith, who is just in from Sawyer's Bar, Klamath county, reports that Robert Burns, of that place, has discovered a very rich gold-bearing quartz ledge in Eddy's gulch, about two miles from Sawyer's Bar. A company has been formed, and the owners of the ledge now consists of R. Burns and his brothers Wm. and D. Burns, D. Casey and James Gould, all old residents of Sawyer's and Wm. A. Farris, the present Superintendent of the Black Bear mine. The newly-discovered ledge prospects exceedingly rich, far exceeding the famous Black Bear.—*Humboldt Times.*

FREIGHT TO BE RAISED.—The Virginia and Truckee Railroad Company are about giving the "crank another turn." Mr. Herington, General Superintendent, has issued notices to the effect that on and after the 1st of next month the rates of freight on lumber will be as follows: From Carson to Gold Hill and Virginia, \$7 per 1,000 feet; from Reno to Gold Hill and Virginia, \$10 per 1,000 feet, or \$75, car load rates. There will now be a chance for teamsters to again make wages.—*Virginia Enterprise.*

SCIENTIFIC PROGRESS.

Interesting Researches--Effect of Electricity on Oxygen.

In a paper, lately addressed to the French Academy of Sciences, M. Chabrier describes certain researches of his, which promise to be fruitful of most important discoveries. Reasoning upon the well-known fact that ozone is simply oxygen so modified as to render it a much more active agent than when in its natural state, the idea struck him that, if oxygen can undergo a change through the influence of electricity, other elementary gaseous substances might also be endowed with a similar property. He accordingly selected hydrogen, and subjected it to the same ordeal, by which ozone is generated. In his very first trials he remarked that, after undergoing electrification, hydrogen presented all the reaction characteristic of ammonia, and that the nearer the wires of the induction apparatus were brought to the orifice of the tube during the operation, the more perceptible became this "activity" of the gas.

This led him to bring the latter in its electrified state into contact with oxide of silver. His first attempt was unsuccessful, he having taken some oxide which had been prepared more than a month before and had assumed a green olive tint. But on repeating it with some prepared on the spot and deposited in a still moist state on a small porcelain disk, the oxide soon became black, and its surface appeared sprinkled with brilliant particles having the appearance of metallic silver. Observing this transformation carefully through the microscope, the shining particles seemed to multiply and then grow larger, assuming the appearance of globules of mercury. This action gradually became weaker, and after a certain time ceased entirely. The experiments being repeated in several ways, it became evident that oxide of silver might be reduced to a metallic state by electrified hydrogen.

Examined under the microscope, after several hours exposure to this new agent, M. Chabrier remarked that the globules ultimately lost their shape, leaving behind a small crystalline skeleton. On exposing them again to the action of electrified hydrogen, he perceived that the globules seemed to have emitted an argentine fluid, which had become solid, and appeared even to have been projected to the same distance. Hence he concludes that the new agent had not only the power of reducing the oxide of silver, but also of forming with the metal thus obtained a fluid of an unstable nature, capable of "spouting" like certain melted substances in a crucible.

SINGULAR CAUSE OF FIRE.—The works of the Rubber Cloth Company, at Nantucket, Conn., were destroyed by fire several weeks ago under the following singular circumstances: The building an old one of wood, was 100 feet or more in length. The cloth is prepared by treatment with alcohol and linseed oil, and, during the operation, is passed over wooden rollers and extended along, for fifty feet or more, into a smaller vulcanizing chamber some thirty feet in length, where it is hung in folds from the ceiling to be dried and heated. The heating is done by steam pipes. Electrical sparks had been noticed in passing the cloth along over the rollers. On the morning in question, which was exceedingly cold, the sparks had been observed to crack louder than usual. A snow storm was in progress at the time. The workman, who was engaged in hanging the folds of cloth in the vulcanizing chamber states that suddenly there seemed to come from his hands a sheet of electric fire, there was an explosion, the place was instantly in flames, and himself and others had to run for their lives. The building and contents were soon destroyed. The theory is that the fumes of alcohol and oil formed an explosive gas in the apartment, which the electrical sparks ignited, just as gas ordinarily is fired by electricity.—*Scientific American.*

LIGHT.—According to the theory generally received at present, the whole universe is an immeasurable sea of highly attenuated matter, imperceptible to the senses, in which the heavenly bodies move with scarcely any impediment. The fluid, which is called ether, fills the whole space—fills the intervals between the heavenly bodies, as well as the pores or interstices between the atoms of a substance. The smallest particles of this subtle matter are in constant vibratory motion; when this motion is communicated in the retina of the eye, it produces, if the impression on the nerves be sufficiently strong, a sensation which we call light. Every substance, therefore, which sets the ether in powerful vibration, is luminous; strong vibrations are perceived as intense light, and weak vibrations as faint light, both of them proceed from the luminous object at the extraordinary speed of 186,000 miles in a second, and they necessarily diminish in strength in proportion as they spread themselves over a greater space. Light is not, therefore, a separate substance, but only the vibration of a substance, which, according to its various forms of motion, generates light, heat, or electricity.

A SINGULAR INVESTIGATION.—Most of our readers are acquainted with those singular little pieces of glass called "Prince Rupert's Drops" or "Dutch Tears," elongated drops of glass, with a slender stem at one end, which, when broken while the other end is held firmly between the thumb and forefinger, the whole mass instantly crumbles into fine grains, producing by the concussion, a stinging sensation in the hand holding it. Dr. De Lanyne has recently communicated to the French Academy of Sciences that, on investigation, instead of finding the glass when broken in irregular particles, like ordinary glass, he found that each particle was in the form of a small cone.

By enclosing the drops in plaster of Paris, he succeeded in breaking them without allowing any of the fragments to change their position. He then found that each particle is a little cone, with its apex always turned towards the point where the force causing the rupture had been applied. The little cones are partly enclosed one within the other, and are remarkably regular in their arrangement, and a similar regularity of rupture is observed in glass rods which break spontaneously in consequence of their not being sufficiently annealed. The rupture may be accompanied by an elevation of temperature of about 70 deg Fahrenheit, and often by a flash of light. Small things frequently furnish a clue to the explanation of great phenomena, and M. Elie de Beaumont thinks that something analogous to what takes place in the little Rupert's drops is constantly going on in the interior of our earth.

MEASURING THE LIGHT OF THE STARS.—IMPORTANT INVENTION.—The photometer has recently been quite successfully applied to astronomy in measuring the light of the heavenly bodies. Of course the instrument so used is quite different from that employed to compare the relative intensity of flames here on earth. The astronomical photometer, invented by Tolner, is based on the polarization of light. By attracting such a polarizing photometer to a telescope, he has been enabled to determine the comparative luminosity of divers heavenly bodies with greater accuracy than had previously been possible.

The special importance of this discovery or invention arises from the fact that the observations on the comparative luminosities of different stars will now be so accurate as to furnish reliable data on which future astronomers will be able to determine what changes have taken place in course of time; changes which are sometimes very great and of the utmost importance to the extension of our knowledge of the nature of the heavenly bodies. As a standard of comparison, he uses the light of a lamp shining through a pin-hole; and in order to be independent of the perhaps variable light of this lamp which may differ on different nights, he compares two stars with the lamp, and only notices the difference between the stars.

SUPERHEATED WATER.—Professor Tyndall makes a very pretty lecture-room experiment, showing the explosive nature of superheated water, or water heated above the boiling point, after all the air has been expelled from it. The Professor takes two test-glasses covered with a bell-jar; in one he puts a small piece of ice, which he covers with a layer of oil; in the other undistilled water, also covered with oil. Both are brought to the boiling point; as soon as the one free of air reaches the degree of vaporization it explodes, dashing the oil over the bell-jar. The water in the second test tube boils away quietly in the usual manner. This experiment has a peculiar significance in connection with the steam boiler explosions are often attributed to the fact that after water has been boiled for some time, it loses the air which was dissolved in it, and when this point is reached it suffers a peculiar modification. Being deprived of air it does not vaporize slowly, but explosively throughout its whole mass.

HEAT OF THE SUN.—There are few things in which physicists so much differ as in their estimation of the temperature of the sun. Some hold that it is not greater than that of the electric arc, (whatever that may be), others double that heat. Father Secchi estimates it at 2,000,000 Fahr., and Ericsson at 6,000,000. Herschel gives the following curious idea with regard to the heat of that luminary. Suppose a rod of ice of sufficient length, but 45 miles in diameter, was projected toward the sun at the inconceivable velocity of ten millions of miles per minute, and under such circumstances as could concentrate the entire heating power of the sun upon the end of that rod, (representing a disk of 45 miles diameter), the advancing rod of ice would never reach the sun, because its approaching point would be melted away as fast as it came!

TO PRESERVE CHEMICALS.—Earthen vessels are constructed with a groove near the top. The groove is filled with castor oil, with which the cover is brought in contact in closing. The connection with the outer air is thereby interrupted. Chloride of lime, for instance, was preserved in this manner for two years, without deteriorating in the least by the absorption of moisture.

PICRATE OF LEAD.—It has been found that alk goods containing picrate of lead frequently take fire in railway transit. Investigation has shown that the fire is due to the picrate of lead, which, under such conditions, ignites with very little friction.

MATCHES WITHOUT SULPHUR, OR CHLORATE OF POTASH.—It has long been a desideratum to secure a match which could be readily ignited without the production of the unpleasant fumes of sulphur, or the dangerous explosive spark due to the nitrate of potash. And it is now reported that a Frenchman, named Eschach, has patented such a match, which can be ignited by rubbing on any rough surface, and which does not become damp when exposed to the air for a long time. The splints are first soaked in a hot solution of some fatty body, and then dipped in a paste of which the following are the constituents: phosphorus, 7 parts; gum, 7; do.; nitrate of lead, 40; powdered glass, 5; water, 10.

EFFECTS OF SULPHUR ON PLASTERING.—We find in the *Builder*, a note on the effect of sulphurous gases emitted from the coal upon plastering, in which it is claimed that the hair in the ordinary plaster becomes the means of disintegrating if unprotected by a covering of a character to resist the gas emitted by the coal, which contains more or less sulphur.

IN AID OF SCIENCE.—Cyrus W. Field has notified Prof. Henry of the Smithsonian Institute, that all announcements of important astronomical observations or discoveries will be received or transmitted by the Atlantic cable free of charge.

MECHANICAL PROGRESS.

Welding Steel.

The property of weldability, as well known, is possessed by wrought iron—not, however, by pig iron; hence it is evident that steel must exhibit a very different deportment in this respect, according as it approaches in its composition the one or the other. Many kinds of steel of a low percentage of carbon weld almost as easily as wrought iron; others with a higher percentage weld with more difficulty; while, finally, pig iron, which is rich in carbon and for which the degree of softening and that of melting are near each other, can either not be welded at all, or only by particular means. Not only does the absolute amount of carbon in the steel determine weldability, but also the manner in which it is distributed through it.

Steel requires a lower welding heat than wrought iron, but if exposed to too high a temperature, it burns, and, in consequence, becomes so friable that it breaks to pieces when hammered. This circumstance is to be taken into consideration in welding steel and wrought iron, which is so often done with tools, rails, etc. This operation is partly in order to produce the articles cheaper, partly to give to the parts most exposed to wear the hardness of steel, and to others the tenacity and inflexibility of wrought iron. In this case the wrought iron is first placed into the fire or both are heated separately; besides, particular fluxes are applied for the purpose of protecting the steel from burning, and to facilitate the unification of various materials.

The most essential conditions to be fulfilled in welding are, that the pieces to be welded possess a pure metallic surface, and that they be properly formed in the first instance, so that they may be united without delay. Where it can be done they are put together as well as possible before they are placed in the fire. The steel must be heated as rapidly as possible and excluded from the air; best with charcoal and good coke, since coals, on account of the fact that they contain sulphur, produce a thin layer of sulphate of iron, which prevents proper welding.

In order that the parts to be welded may remain pure in the fire, they are covered with a proper material, which forms a liquid, protective layer, and at the same time dissolves the oxide. For this purpose sand or clay is used, by spreading them upon the parts in form of a paste; the operation succeeds much surer and easier with less fusible coverings. For cast steel, ground glass, heavy spar, or anhydrous molten borax serve well. For English cast steel, common builders' mortar may be used, or, in lieu thereof, a mixture of clay and sand.

Aside from these more simple means, special welding agents are employed, the composition of which permits the formation of an easily fusible slag. Among the mixtures recommended we mention the following: 64 parts borax, 20 parts sal-ammoniac, 10 parts yellow prussiate of potash, 5 colophony. These ingredients are heated with $\frac{1}{2}$ litre water and some alcohol, until dry. Another preparation is composed of 41.5 parts boracic acid, 3.5 salt, 15.5 prussiate of potash, 8 calcined soda.

Habich prescribes 7 anhydrous prussiate of potash, 2 calcined soda, and more or less burned borax, according to the nature of the steel. Ermer recommends, to dissolve in water, 8 borax, 1 sal-ammoniac, 1 yellow prussiate of potash, and to evaporate the solution at a low heat to dryness. When strongly heated, violent explosions may occur by the formation of chloride of nitrogen.

In welding, at first light, then heavy blows are given, so that the slag may escape from the joints, whereupon the outer surfaces are united.

THE BESSEMER PROCESS FOR STEEL-MAKING.—It is rapidly gaining ground, not only in England but also on the Continent of Europe.

Cannon Casting in Sweden.

Special attention is paid in Sweden to the production of what is called "cannon iron," or cast iron, made especially for the manufacture of heavy artillery. The ore from which this iron is smelted is taken from three different mines, and from those only. From one of these mines, Foerola, 80 per cent of ore is taken and mixed with 10 per cent each of ore from Nartorps and Stenoholm, from which proportions experience has shown the best results can be obtained.

The iron so obtained, exhibits an amount of elasticity extraordinary for cast iron—a quality of great importance in cannon.

The natural superiority of the iron is largely improved by a peculiar mechanical device employed in the casting. In this process instead of pouring the metal directly into the mold it is poured into a receiver from which it rises in the mold, from the bottom, with a rotating motion around the core, which is hollow and kept cool first by a stream of water passing through it, which is followed by a current of cold air, during the process of cooling. With every large cannon, a small one, from 4 to 6 lbs calibre is cast, whereby the calibre of the large piece can be comparatively ascertained.

INCOMBUSTIBLE AND INDESTRUCTIBLE WOOD.—Quite too little attention is paid to the preparation of woods for construction purposes so that it may be rendered comparatively combustible and indestructible to ordinary sources of attack by rot, insects, etc. By employing some of the many preparations, already known, wooden dwellings may be made almost as safe from fire as those constructed of brick or stone, and as little liable to decay as though they were made of iron. The time will soon come when these desirable qualities will be added to ordinary lumber, for such a small addition to its first cost as to place such prepared wood within the means of any person who can build a house or wharf.

In connection herewith we refer to still another invention in this direction, by one Macomber, of London, who is said to have devised a plan for rendering wood both combustible and indestructible by insects or decay, by a single operation. He takes lumber in its green state, and having first, by hydraulic or steam pressure, or otherwise, expelled the sap, replaces it by a chemical composition of his own invention which he keeps secret, and which is to destroy the inflammability of the material. Not only this, but the liquid is to act as a preservative in other ways, preventing the wood so treated, rotting from the attacks of worms or insects.

COAL CUTTING MACHINERY.—The improvements in coal cutting machinery are such as to bid fair to work a most important revolution in coal mining. It is claimed that they have a new machine at the Helton colliery, in Durham, worked by compressed air, by which, it is said, 60,000 colliers will be enabled to produce the same amount of coal as the 300,000 now employed. Of course we should allow something for the distance which that report has traveled to reach the Pacific Coast; but the general testimony is that machinery will soon be made to do all the "colling" in coal mines, which form a large portion of the labor, and in very narrow seams, we may say, the principal portion. The saving thereby made in the waste of the coal is also a very important item.

CAST IRON PRODUCT OF THE WORLD.—The annual consumption of iron has reached an enormous figure and is still rapidly increasing. A careful estimate of the product of cast iron for 1871 is given in tons as follows:

Great Britain.....	6,570,000
United States.....	1,912,000
France.....	1,350,000
Germany.....	1,230,000
Belgium.....	895,000
Austria.....	450,000
Russia.....	330,000
Sweden and Norway.....	280,000
All other countries.....	347,000
Total.....	13,315,000

From the above it will be seen that the annual product of Great Britain reaches within a fraction of the total product of all the rest of the world.

FORCE OF THE WIND.—A singular occurrence took place at a point on the Jersey shore, nearly opposite New York, a few days since, strongly illustrative of the force exerted by the wind. While a large number of men were at work upon a ship on the stocks a gust of wind suddenly lifted the open house which was employed to roof over the work and carried it entirely away. It was 250 feet long, 80 wide and 80 feet high. Singularly enough no one was injured by the sudden removal.

BRONZE.—The doom of bronze, as a material for rifled guns, says the *London Daily News*, has been sealed. The manufacture of seven-pounders in that metal for mountain and boat service has now been given up, and orders have been issued for the construction of steel 7-pounders instead. The failure of bronze has been a great disappointment to its advocates, who only a few years ago were full of confidence in the perfection of their favorite material.

HEAVY ARTILLERY.—As an evidence of the possibilities in the way of the construction of heavy artillery, it is stated that Mr. Bessemer says he is prepared to supply guns that shall fire balls of five tons at the rate of one a minute, and to construct a gun to fire a ten ton ball.

Julia.
Letter of the 5th says the progress on the different drifts during the past week was 9 feet, making the total length from the shaft 196 feet. The rock continues very hard, all blasting rock; drift north from main drift, starting 98 feet from the shaft, made 4 feet during the week, making 90 feet from main drift north. Are crosscutting both east and west, all in ledge matter, looking very well; will develop something soon probably.

Ophir.
Letter of the 8th says the ledge of quartz found a day or two since in east drift of the 1665-foot level lies 345 feet east of the shaft, and well placed between clay and walls. The drift is all in ledge matter which, although assaying but little as yet, promises well. Drift east from the bottom of the winze from this level will cut the same ledge in about 20 feet. The body of quartz found in second station looks well, but has not been reached yet by the drift from the bottom of winze. No change elsewhere.

Pioche.
Letter of the 2d says they have shipped about 100 tons of ore to the Meadow Valley mill. They were to start on our ore yesterday. Have found another cross-cone in the bottom in driving to the east. Car samples for the 31st were \$297.04.

Pioche-Phenix.
Letter of the 31st says the new shaft is now down a depth of 60 feet. The contractors came on the ledge yesterday. It is now 2 1/2 feet wide, and assays \$116.23.

Page & Panaca.
Letter of the 31st reports a change, at last, in the mine. They struck in the drift, 601 feet from the shaft, a small ledge or seam of ore, assaying \$6.93 per ton, and it may possibly be the main ledge, but small at that point. The water has been as some, causing us to timber a portion of the drift.

Raymond & Elv.
Letter of the 1st says the eighth-level drift southeast is 55 feet in, and through large crosscut; 7th level drift east, 116 feet; drift west 86 feet—good ore coming in; east winze down 29 feet. On 6th level, west from shaft, we are sinking a winze which is now 21 feet deep, with two feet of good ore in the bottom. The various stops are looking and yielding well. Traces to old Panaca shaft are nearly completed and are entirely satisfactory. The mills are running well, with good supplies of ore on hand. Will run both of the mills through this month on third-class ore.

Dispatch from the Superintendent under date of April 4th says: "I shipped yesterday \$11,000." This makes the total for the month of March, \$24,391.

Rye Patch.
Superintendent writes under date of April 7th: "I forward this day one bar halion, weighing 614 ounces, and will make another shipment to-morrow. I am putting in another pan to-night, and as soon as I receive the tabs ordered at Miners' Foundry for two additional pans you may rely on daily halion shipments. The mine is promising better every day. The new incline is connected with north drift; hoisting gear and tracks are in splendid order, and ore is accumulating in great quantities on the dump."

Silver Peak.
Letter of the 2d says there is no change in the mine. The drift both ways continue in good ore. Can probably make arrangements with the five-stamp mill at Bullionville to start on our ore. The average assays for the 31st were \$115.63, and for the 1st inst., \$167.63. Are confident that the mill will pay, and are sure that we have a good mine.

Sierra Nevada.
Letter of the 5th says that everything is running in good shape. The mine prospects and looks as well as at any time for the past three months. The northwest body of ore is holding out very well; the average width is about five feet; opened about 50 feet in length, and about 40 feet high. This ore will pay from \$6 to \$10 per ton. Mill runs splendidly. They worked last month 1,357 tons of ore.

Savage.
The weekly report, for the week ending April 6th, gives the following summary of operations: Ore extracted from the mine, 213 tons 1000 pounds; average assay value of the ore extracted, \$24.30 per ton. The ore was taken from the following sections of the mine: north mine, 2d station, 139 tons 1000 pounds; south mine, 13th station, 54 tons.

Woodville.
Letter of the 3rd says the mine is looking well throughout; plenty of high-grade ore in sight; south drift is now in 225 feet on the ledge. Ore is 4 feet wide; north drift is in 80 feet; the ore is improving as we get north. The other levels are all looking well.

New Incorporations.

BETTS' SPRING MINING CO.—April 8. Object: To manufacture and vend carriage and other springs. Capital stock, \$50,000, in shares of \$100 each. Trustees—Louis Lierson, Frank Locan, Alexander Austin, Gustave Holland, Henry Marshall.
EDDY G. AND S. M. CO.—April 8. Location: Mud Springs, El Dorado county. Capital stock, \$250,000, in shares of \$100 each. Trustees—Louis Lierson, Frank Locan, Alexander Austin, Gustave Holland, Henry Marshall.
PRAIRIE STEAM PUMP CO. OF CALIFORNIA.—Object: To manufacture and vend pumps of the Prairie patent, described in the last issue of the PRESS. Capital stock, \$150,000, the whole of which has been actually subscribed. The Directors are, L. F. Rankin, A. G. Stiles, R. T. Knox, Eugene N. Riatte and A. V. Brayton.

CENSUS OF MANUFACTURES.—The last census furnishes some instructive and suggestive figures on the manufacturing interests of the United States. New York and Pennsylvania lead the van. New York and Philadelphia are the leading cities, each producing about three-fifths of the manufactures credited to its respective State. Thus New York City, with 129,577 operatives, produced in 1870 \$333,951,520 of goods, whilst Philadelphia, with 95,421 operatives, produced \$322,004,527. These two cities in 1870 manufactured more than one-seventh of the entire product of the country. The third in the list is St. Louis, with a product of \$158,761,018; the fourth, Middlesex County, Massachusetts, which includes Lowell, and returns \$113,147,270; the fifth, Suffolk County, including Boston, \$111,380,840; the sixth, Essex County, which includes Lawrence, \$96,990,868. Following them in regular succession are the respective counties in which are located Chicago, Pittsburgh, Providence, Cincinnati, Worcester, Brooklyn, Baltimore, Newark, New Haven, San Francisco, Hartford, Manchester (New Hampshire) and Louisville, the latter having \$20,364,360 annual product.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned:

AMADOR COUNTY.

KENNEDY.—Amador Ledger, April 5: It has been some time since we have mentioned this mine, but it has been running smoothly and crushes out its regular \$20,000 per month. The new shaft is progressing finely, and is now about 280 ft. down. The ledge in the old shafts are improving and the rock is richer and of better quality than formerly taken out.

CALAVERAS COUNTY.

GRAVEL MINES.—DURIEA HYDRAULIC.—Calaveras Chronicle, April 5: Work is being steadily pressed forward with satisfactory results. Three hundred inches of water, with a pressure of 250 ft., are conducted to the claim in a 12-inch iron pipe and precipitated against the rock through a 3-inch nozzle. It is knocking a hole in Stockton ridge large enough to contain the pyramid Cheops.

BROWN & CO.—The mine was worked a number of years ago and found to contain a large amount of pay gravel; but the tunnel run at that time was too low necessitating work through a chute, which increased the expense so inordinately that the ground was finally abandoned. Messrs. Brown & Co., are now engaged in running an incline to reach the diggings, and have their work so nearly completed that they will be taking out gravel in a week or two.

BRACKETT & CO.—These gentlemen are busily engaged running a new tunnel to tap the channel higher up the ridge. It is already in a distance of 250 ft., leaving but 30 to run. They expect to strike gravel in about 3 weeks. A vast amount of money has been taken from this mine within the past five years, and when the new tunnel is completed the yield will be greater than ever. A ten stamp mill is to be put on the claim.

SIMPSON & CO.—Their mine is the handsomest and most substantial piece of workmanship of that character we ever saw. It has a grade of about 1 ft. in 12, and is supplied with the best known appliances for saving gold. A 12-inch iron pipe is used to convey water to the mill, and 300 inches are to be used—having a fall of over 200 ft. There are two strings of sluices connected with the mine, leading to different faces on the bank. The ground was worked at several years since, and paid tolerable wages with water 50 cts. an inch and the piddling manner in which operations were conducted.

MORSE & CO.—At the head of the gulch the tailings have been washed away down to the bedrock, and the work of shoveling the rock into sluices will be commenced shortly. There is undoubtedly a large amount of gold accumulated in the bottom of the gulch, as enough cleaning up has been already done to prove that the tailings are rich.

WALTERS PERCIVAL & CO.—At present they are engaged in digging a new headcut out, which, when completed, will enable them to work to much better advantage than heretofore. Water will be turned on again shortly, when we think the mine will give a good account of itself.

MOSQUITO DISTRICT.—The levels of the Dolly Varden are in good milling ore. Some 300 tons of ore on dump. The Woodcock and Lefranchi (on the same ledge), are expected to start up as soon as possible. These two mines are located on a strong vein of low grade ore, say, \$250 per ton. The Woodcock has been worked but little although the mine shows well. The Lefranchi has paid as high as \$47 per ton and has been worked to water level.

WEST POINT DISTRICT.—Ohio Con. down 130 ft. Ground easy but some difficulty is experienced from the pump choking with sand. Free gold can be seen in the ore. A drainage tunnel has been run from Deer Creek to the mine paid \$37 per ton. The Carlton mill will run on Lone Star ore. The mine looks well. The drain tunnel of J. Griggs is within 50 ft. of the nearest vein. Pascoe & Co. piping for float from the French lead, with good results. Wickham & Smith are building an overshot wheel, 34 ft. diameter, 3 ft. breast. The wheel will furnish the motive power for a sawmill—machinery will be added, to crush ore.

GWIN.—The contractors for sinking the main shaft in the Gwin 100 ft. deeper have commenced work. The ledge develops splendidly as labor progresses. There is no diminution in the yield of the mine.

HUNDON.—The work of sinking the shaft is progressing favorably, although the progress made is not so rapid as during the first 50 ft. of the count.

WEST POINT DISTRICT.—Calaveras Chronicle, March 29: The Ohio Con. is in full blast again. The new pump works well, and the ore in the bottom of shaft looks fine. Henry & Co., who have been driving a tunnel to tap two large veins at considerable depth are now extending on one of the veins. S. Haskins is working a fine vein at Summit Flat. Another rich strike has been made on Lone Star. A winze, in the middle tunnel, develops a seam of ore 1 ft. thick, and worth at least \$100 per ton. The strong chimney in the upper tunnel turns out some ore worth \$150 per ton. The average of the ore, say 8 ft. wide, will realize \$40 per ton. Roads are being cut from both tunnels to haul ore to the custom mills. The Harris at El Dorado, is improving in quality of ore, and developments are promising. The Anglo, Calaveras & Co. owners, shows very fine specimen ore. The owners estimate the ore on dump at \$75 per ton.

GOON HOPE.—We learn that hoisting works are to be put upon the Good Hope at Mosquito as soon as possible.

SYME.—We are pleased to learn that a company of English capitalists have purchased or leased the Syme near Campo Seco, and will commence work immediately. The mine has been prospected considerably, and so far as work has been done shows well.

MOSEN & CO.—Are steadily at work in their claim in Spring Gulch and we understand are doing first-rate. They are washing the tailings that have accumulated in the gulch from the hydraulic in the ridges on either side. We learn that the claim is paying handsomely—a merited reward for the perseverance and energy of the proprietors.

CONTRA COSTA.

STROCK COAL.—Contra Costa Gazette, April 5: The Muir brothers, who have been at work for some months with night and day shifts of hands running a tunnel for the Black Diamond vein, on their property near Kirker Pass, have got in something more than 160 ft., and on Friday or Saturday last, struck a ten inch vein of excellent coal. The calculation started on, as we understand, will carry tunnel something more than 100 ft. further in to strike the Black Diamond vein. Before running further, however, air stops or other provisions for ventilating the tunnel will be necessary. The tunnel will bring the coal out on this slope towards water, for shipment; and we hear that work is soon to be resumed in the San Francisco mine.

EL DORADO.

CRAM AND BERRY.—Placerville Democrat, April 5: This mine exhibits some very rich rock, and has so far paid all expenses of sinking a shaft 100 ft., which was done last summer. During the past winter operations were suspended for want of proper machinery for keeping out the water. As soon as the weather is satisfactory, the work of sinking will be recommenced. **GRACE QUARTZ.**—This mine is owned by H. A. Randall & Co., who after a month's rest and settlement of weather, have again resumed operations on their shaft, 120 ft. deep, and are sinking between two nice walls, 7 ft. apart, on a 2-ft. ledge, widening as they go down. The quartz is of bluish cast, and gold can be seen with the naked eye all through it, in thin layers. The rock assays from \$12 to \$100 per ton.

KLAMATH.

DISCOVERY.—Humboldt Times, March 29: Mr. James Bell, who is just in from Sawyer's Bar, reports that Robert Burns, at that place, has discovered a very rich gold-bearing quartz ledge in Eddy's gulch, about two miles from Sawyer's Bar. The newly discovered ledge prospects exceedingly rich, far exceeding the famous Black Bear.

KERN COUNTY.

PAPPOOSE MINES.—Havilah Miner, April 5: This mine, discovered last summer, near the celebrated Bright Star, has interested Boston capitalists, who propose to erect a ten-stamp mill near the site of the mine. A fine grade of quartz is being extracted, and a run will be made of the old mill soon.

PLACER DIORINES.—Schubert has been in town this week, and informs us that the Danascus placer diggings are producing about \$1 to \$2 per day. Water will last about 2 months yet. Voegel is doing well and working like a Trojan for a home-stake.

SAN DIEGO COUNTY.

ANOTHER RICH STRIKE AT JULIAN.—San Diego Union, April 3: A report comes from Julian City that the Swain brothers, who are located on the north bank of Deer Creek, opposite the Providence, have discovered a rich ledge of quartz is said to be streaked with free gold, and to make as fine a showing as that from the celebrated Chairot mine. They call the new discovery the "Tom Scott." The ledge is two ft. wide where opened, and looks well. The lucky finders have commenced sinking a shaft, which is now down to a depth of 20 ft.; and they announce their intention of putting in an engine to drive the mine for about 24 hours. The shaft is down 75 ft. It is being sunk perpendicularly, to cut the level at the depth of 150 ft. from the surface.

NEVADA COUNTY.

NEVADA.—Nevada Transcript, April 5: The Nevada Quartz mine is what was in early times known as the "Agassiz mine," and is located on the north bank of Deer Creek, opposite the Providence, and opened into the tunnel of the latter. The rock is rich and filled with sulphurets, and the mill is now at work upon this rock. The mill was thoroughly overhauled and repaired. The battery has a simple self-feeding arrangement, which saves considerable work, the feeding being regulated by the drop of the stamps. They have a rock-breaker, rubber rollers, and a sulphurets sifter, and other arrangements for saving gold.

MR. MITCHELL. of this city, has one of his pans in this mill. He catches what sulphurets escape the mill by a simple box and double trough. The sulphurets are worked in his pan, which consists of a cast iron pan with an oval rim, hollow underneath, and in the bottom of which shoes run for grinding. The pan is depressed in the center, the light sand is carried by the water over the rim of the pan, and the sulphurets settle in the bottom. The quicksilver is not subjected to the grinding process, and is all saved. This pan is pronounced by those who have seen it the best in use.

Now that the mine has been opened below the bed of the creek, the prospects are better than ever before.

GOLD TUNNEL.—This mine was worked many years ago. Some rich rock was taken out at a time when quartz mining was in its heyday, and afterwards it was given up and laid idle for some time.

Eighteen months ago, J. H. Helm took charge of this mine, and erected hoisting works of a substantial character, with a 25 or 30-horse power engine to run them, and making other improvements.

The incline has been sunk 450 ft. through rock about as hard as cast iron, and a tunnel run north 160 ft. A drainage tunnel has also been run from Deer Creek to the incline, so that the water has to be raised 250 ft. For the last 150 ft. in the north tunnel they have been running upon a splendid ledge of quartz, rich in sulphurets, and which will pay first rate. They have on the dump now 100 tons of rock, and few mines in the county can show a better pile of quartz.

We understand they contemplate building a mill upon Deer Creek below the mine, to be run by water power.

The prospects of the mine are most excellent, and there is now in sight enough ore to last two years.

THE MURCHIE MINES.—The mining claims of the Murchies, father and sons, are located on the east bank of Little Deer creek, a short distance above this city. Recent developments have demonstrated this to be one of the best properties in the State. They own and work three quartz mines and a gravel claim, all paying well.

LONE STAR.—The Lone Star was discovered about a year ago in running a tunnel in their gravel claims. They ran last season about 900 ft. and found 155 tons of rock, which averaged over \$21 per ton. This tunnel was on the Little Deer creek side. They commenced a new tunnel from the Big Deer creek side last winter, and ran 400 ft. at right angles, not expecting to strike the ledge, but intending to open a tunnel for their gravel claims. But they struck the ledge in this tunnel 300 ft. ahead of the old works, and found it 12 ft. thick, and as rich as when they left it in the old tunnel. The ledge and face of the ledge show free gold all through, and they can pick rock which will yield \$500 per ton. They crush all between the walls, and get from \$20 to \$30 per ton. They use no machinery, and the expense of extracting and working the ore does not exceed \$5 per ton.

INDEPENDENT AND BIG BLUE.—These two ledges, on the east of Big Deer Creek, are worked by one incline. They are taking out first grade ore, and the mines look well.

GRAVEL.—The Murchie gravel mines are located on the hill above the Lone Star, and the ledge runs into the gravel. The gravel is rich, and in washing this season they have struck quartz boulders which yield large amounts of money. The gravel also pays well.

The mill is located on Big Deer Creek, and is run by water power. The eight stamps are kept in operation day and night, and do not begin to keep up with the work. The owners propose to build a new 30-stamp mill soon, which will also be run by waterpower. The creek furnishes power enough to keep both mills in operation nine months in the year.

The prospect in these mines is most flattering. They now employ from 20 to 40 men, and in a few months will probably require many more to do the work. They have already rock enough in sight to last several years, and yet the mine can hardly be said to be fairly opened.

HOME.—This mine is located on Deer Creek, at the mouth of Wood's ravine. It is owned by Thomas Findley & Co. Last week they struck a magnificent ledge, which showed very rich in free gold. Unfortunately, shortly after they struck this rich strike, the pump broke, and while getting it repaired the mine filled with water. They are now engaged in pumping out.

ROCKY RAVINE.—Nevada Transcript, April 5: Some excellent prospects in quartz have been discovered on Rocky Ravine, north of Rush Creek, and in the vicinity of Green's ranch, about 2 miles from this city.

YELLOW DIAMOND.—This ledge was located a year or two ago, and two tunnels were run upon the ledge. Excellent ore was obtained and the indications were splendid, but for some reason the owners stopped work. We are informed by a gentleman who recently visited the mine that there are at least 300 or 400 tons of excellent rock in sight in this ledge. The ledge has been tapped in 4 different places and in each of these places it shows rich sulphuret rock.

SOUTH EAST EXTENSION.—Dr. Hughson & Co. have lo-

ated the south east extension of the ledge. On this claim they have now a tunnel in progress and are running upon a 3 ft. ledge. We have seen some rock from the croppings which is rich with free gold. The ledge is near the Green claim which is now yielding the biggest kind of pay.

GREEN'S LEDGE.—This claim is the second extension of the Yellow Diamond. The ledge at this point where it is working is decomposed, consisting of ochre and bluish quartz. They ground sluice it to the depth of 8 ft. and run off this decomposed stuff. A gentleman who saw several pans of this dirt washed says: he saw from \$3 to \$5 to the pan taken out, and the pay runs as high as \$5 to the pan in some places.

THE WORK AND PROSPECTS.—The Yellow Diamond is not now being worked, but both the other claims are, and their success will encourage others to take hold and prospect in the vicinity. The Second Extension will soon have out a crushing, and it is estimated that Green will in a short time be able to clean up at least \$1,000 for a short run at very little expense.

PENNSYLVANIA.—For some months past this mine has been in charge of Mr. Cliff of Grass Valley, as Superintendent. When he took charge, the mine was in a very bad condition, in consequence of the owners having previously used it for working it. The ore was taken out, but never it could be reached without reference to system or cost of extraction. Mr. Cliff has sunk one level of 100 ft., and run two tunnels each way, and he is now running another for the purpose of opening the mine. He is also running a tunnel north, where the largest body of ground belonging to the Pennsylvania lies, and which has never yet been opened.

ANOTHER STRIKE.—A man named Jackson went to work in the bottom of an old prospect hole on Red Hill, recently, and struck a stringer which showed pure gold. A gentleman informs us that he can make from \$20 to \$30 per day working the rock in a hand mortar, and he thinks Jackson has struck the edge of a big pocket.

MYERS' RAVINE.—A rich ledge of quartz, which has been struck on Myers' Ravine, beyond Selby Flats. We saw some very rich specimens from this ledge a day or two since, and we understand they will soon have a crushing out.

BARS OF GOLD.—Grass Valley Union, April 9: The ledge skimmed up the amalgamators of the mill on Saturday, after six days' run, and gold to the amount of about \$17,000 was cleaned up.

The Eureka, after a six days' run with ten stamps, gave a chunk of gold worth \$9,000. The bars are in San Francisco, and the mint is making the gold into coin.

TUOLUMNE COUNTY.

LADY WASHINGTON.—Tuolumne Independent, April 5: This mine, at Summitville, is owned by a California Co. Their tunnel has reached the distance of 350 ft., and the miners are running up an air shaft which will be, when finished, about 250 or 300 ft. from tunnel to surface. They have laid a track 2,200 ft. long from the mine to the mill. "Grizzly Mill," which they have leased for a year, and will put in operation in about a month. The vein looks well and ranges from 2 to 5 ft. wide.

RAIN HIDE.—Near Jamestown, has been bought by an English Co., with its corporation office in New York. They have commenced operations, and the mine will be re-opened on a large scale. The present shaft, which is nearly 400 ft., will be pushed 300 ft. further on the vein, besides sinking several smaller ones for carrying the ore. The present engaged pumping water out of the old shaft. The vein is considered on the "mother load," and ranges all the way from 5 to 20 ft. wide.

LANNES & CO.'S MILL.—At Soulsbyville is in full blast, crushing quartz gravel which came out of the Gison at that place. The hoys are making it pay.

AT THE NEXT.—At the next, a running parallel with the Soulsbyville vein, is being opened up. The Company have been getting out and crushing rock with favorable results, and work is still progressing.

LOUISIANA.—Near Cherokee, owned by Capt. Lombardo, has recently been sold to Lafayette Maynard of San Francisco, conditionally. The purchaser is to furnish the vein prospect, and work the mine for one-half of the same, or by paying \$50,000, but the owner is purchasing the whole of the property. Work will shortly be commenced.

GOLDEN GATE.—In a visit to this mine, a few days since, we found the Superintendent, hard at work with his men, driving the tunnel, which is a splendid piece of work, and is now in 150 ft. They expect in about two weeks to strike the ledge, and further on the drift where the chute is. In this shaft, at a depth of 40 ft., the vein is 6 ft. wide, and prospects from \$10 to \$500 per ton. Near the surface it only prospects from \$5 to \$10. If it increases in like ratio, at 150 ft. deep, where the tunnel will tap it, the yield will be immense. The contract is to run the tunnel 300 ft. with vein 20 ft. wide, hence, the surface; but at present they will go to the first shaft as above stated.

SPINO GULCH.—Sonora Democrat, April 5: This mine is being quickly worked, its promise of richness improved rapidly with every development. During March, 100 tons of ore was reduced, in nineteen days' running, yielding 18 1/2 ounces of gold of about \$3,000 value. The vein from which the ore was taken is 15 ft. in width. The company are now extending their tunnel 75 ft. North and erecting hoisting works.

Nevada.

BELMONT.
EL DORADO CON. CO.—Reese River Revue, April 5: This company made their monthly clean up for March. They have reduced about 600 tons of ore from the company's Arizona mine during the month, and have shipped over \$82,000. The mill will soon commence on the rich ores from the El Dorado mine.

EL CHIMNEY.—The late strike in the El Dorado mine 125 feet north of the main incline is proving to be an immense deposit of black sulphurets ore. This body has been drifted into 100 ft. in the 340 ft. level, a winze sunk 40 ft. into it, and the 400 ft. level is into the same body 20 ft. The ore in the 400 ft. level is getting better every day. The whole drift, 550 ft., is in the pay strata with water foot wall not showing in sight. This is admitted by all who have seen it, to be one of the largest chimneys of sulphurets ore ever found in Eastern Nevada. The ore averages about \$180 per ton. The south body in this mine increases in size as work progresses, and the ore holds its average richness, paying as it goes to the mill about \$100 per ton for the whole vein.

BELMONT CO.—Are stopping in the 190 ft. level in the Onfield mine. The lately-discovered body of ore about 700 ft. north of the main incline is much more extensive than was at first expected. The hoisting works on the Highridge shaft are all framed and ready to raise. As soon as the machinery is ready to raise the ore a full force will be put on and the mine will be thoroughly opened.

MONITOR CO.—Are stopping out in the upper levels. The supply of first class ore is holding good. They have sunk two winzes from the lower tunnel level, north of the tunnel, 100 ft. deep; are now drifting each way from the winzes. Monitor mill running steadily on Monitor ore, and working about 70 men.

NEW DISCOVERY.—Frank Stenler, in digging a foundation for his cabin, cut into a strata of fine chloride ore. He made his location at once, and this morning commenced sinking in good earnest. He has already taken out several hundred pounds of splendid ore. This location lies midway between the Monitor and El Dorado mines, and is in just the place to prove of immense value to the lucky owners.

WASHOE.

WASHOE.—Gold Hill News, April 5: Sinking the new shaft is making fair progress, the entire size of the shaft in good ore, showing plenty of rich sulphurets. The ledge continues very solid and hard, requiring continual blasting.

BELCHER.—Daily yield 440 tons. Eighty tons per day are taken from the 1,300-ft. level, through the Yellow

Ventilation of Mines.

This important subject was animatedly discussed at a meeting of the Scientific and Mechanical Society at Manchester, which was evoked by a paper with this title, by Mr. Haoking. The defects of ventilating by means of rarifying furnaces were pointed out. Exhaust fans were said to be found uncertain, on account of the wear and tear; and the liability to breakage and stoppage, and steam-jets—as they had hitherto been applied—were admitted to be a failure. It is, however, a fact worth knowing, that the steam-jet has lately been very successfully applied by Mr. G. L. Scott, of Gorton to a mine in Wales. Unlike previous attempts, the jets have, in this instance, been placed on the surface, sideways to the up-cast shaft, the mouth of which is sealed. A number of plain cast-iron cylinders are placed in an upright position, with a steam-jet applied at or near the bottom of each, steam being supplied by two boilers, one of which is kept in reserve. Here we have the whole apparatus on the surface, moving parts being entirely absent, and the danger of an underground furnace avoided also. The arrangement is said to be quite a success.

Bathing in the Breakers.

At Hawaii, Sandwich Islands, a favorite amusement of the natives, and foreigners who have attained the art, is swimming in the surf and diving beneath its foaming crests as they successively chase each other to this shore. Our illustration depicts a merry group of native girls each with their surf-board on which they rest, dive or propel themselves along with inimitable grace, ease and safety. A writer in the *Illustrated Press* says of the scene:

Hoomauna and all the rest of them are off for the beach now—they say the surf is good to-day for bathing. Kapello has gone, and beckons us. We are good swimmers, and why not, with the modest though narrow tapa that hinders nought in action or figure, around the middle of each of us?

A merry, lively crowd. Noise of surf and laughter, action, motion, grace. The breakers are certainly stiff; they knock you over again, without the least ado, until you learn to bestow yourself properly—as the natives do. You quickly learn to dive under each one as it comes along, and to catch your breath in time to be sharp "end on" for the next. That trick learned, and you presently begin to laugh at the terror of Neptune yourself. You venture out; you are all right. Why should anybody get drowned in the breakers.

Hoomauna comes sailing by on her surf-board at railroad speed. You try it again and again, but the breaker refuses to pick you up. You get tossed every time. There is an art in it more difficult to acquire than skating.

In sheer animal spirits you strike out for the farthest line of breakers beyond the outermost swimmers. One of the natives beckons you back, but you do not understand what she says or means. Kapello enlightens you after you have dressed. "You ought not to have gone out there—it is deeper, and the sharks come in as far as that."

APPLICATIONS FOR DISINCORPORATION.—The Eberhardt M. & M. Co., White Pine, has filed a petition in the County Court for disincorporation. The reasons set forth are that the mines and property of the corporation have been sold. The application is made by order of a vote of the stockholders on the 27th of March, at a meeting held that day, at which more than two-thirds of the capital stock were represented. The corporation has no outstanding debts, claims, demands or liabilities.

The Aurora Consolidated S. M. Co., has filed a similar petition, a majority of the shareholders having voted to disincorporate.

STRIKE.—The Reese River *Reveille* states that a short time ago a vein of ore was struck in the cross-cut running north-east from South America shaft on Lander Hill. Seventeen tons of ore were taken out in running a drift seventeen feet on the vein. The rock was not assorted, but every pound taken out was worked, averaging \$198.38 per ton. The Manhattan Company had just completed the construction of a cage for the shaft, and about two tons per day of the same quality of ore is being taken out.

An oxy-hydrogen flame furnace of Steven's patent will shortly be erected at Eureka, Nevada.

Little Cottonwood Mines.

A correspondent of the *Alta* writes as follows from Little Cottonwood, Utah: Last Thursday, in company with some others, I started for Granite, chartering a dog trail, similar to the Laplanders, and proceeding with racehorse speed over the frozen snow. After twenty minutes' ride we arrived at Tannersville, just four miles, although in many places our trail was uneven, requiring some considerable caution in the attitude in which we declined to prevent numberless summersaults, maimed limbs, splintered ribs and cracked craniums.

At Tannersville the snow was melting very fast, and we had not been gone long from there when a snow-slide came down from above the old Buel smelter, taking away the engine-house and lodging in the trail. This is the first slide that has occurred there for years, and was very likely caused by some loose rock moving from a cliff above.

Last Saturday a large force of men from here and Granite opened the road from Tanners to Granite for wagons, shoveling out the snow and ice, which has greatly improved them, and aided not a little to the shipment of ore.

The Granite Quarry.

This is the most natural and extensive granite quarry in Utah, and perhaps will equal any in the world. On each side of the cañon, and for miles in length, are solid mountains of this rock, and of superior quality. It is from this quarry that the Mormon Temple is to be reared,

gold along the bed of the Creek between here and the mouth of the cañon since the first silver mines were opened, but with no great success. Of late a report is circulating that gold has been found below Tannersville, but as no proof can be made it is thought to be a humbug; yet the discoverers say they will prove their statements as soon as the snow will allow them to proceed further.

New Arrangements for Hoisting.

At the Minnims Colliery, at Willenhall, belonging to Mr. Matthew Tildesley, some winding machinery has just been put up, which is attracting much attention in the locality, and that deserves to be widely known, for it seems to be applicable to pits of which the depth is not very considerable. The machinery embraces not only compact winding gear, but likewise the means of preventing over-winding, that merit the consideration of colliery engineers. Boiler, engine and winding gear are all at the pit's mouth, and cover a space of only a few yards square. The engine and boiler are both under one roof; the grate is constructed so far as to effect complete combustion, notwithstanding that the slack used has hitherto been regarded as bank refuse. The boiler is vertical, and possesses a large heating surface of 250 feet. The engine also is vertical, bolted to a frame standing on one side of the shaft mouth, where it works direct a drum fixed over the pit on another frame. On the opposite side of the shaft is the fly-wheel, and to this wheel is attached a brake, which securely grips it until the

GIRLS BATHING IN THE SURF, AT HAWAII.

Many thousand tons have already been sent thither at a very great expense, the work having been going on for years, and, that, too, by the slow process of ox teams. Now that the railroad is nearly completed, this immense labor will soon cease, as the cars will pass along by the foot of these large granite mountains.

The Flagstaff Smelting Works.

These furnaces have been in operation for nearly three years, being expressly built for the smelting of the Flagstaff ore, which has supplied them almost exclusively from the beginning. The main building is 60x80 with an engine house and several other small buildings for the convenience of the work. They are now lying still for want of fluxing ore and coal.

The Davenport Smelter

Is situated on the south side of the creek, opposite the Flagstaff Works, and is 40x70 feet, supplied with two furnaces, the most complete in the Territory, and when in running order, works to a charm. They are now lying idle for want of ore. This valuable piece of property belongs to the Davenport Mining Company, but intends to do custom work when not supplied with their own ore. They are now paying ten dollars per ton for the hauling of the ore from here to the smelter, two dollars per ton more than any other mine in the district. As soon as they get 500 tons the smelter will commence work, which will be in a few days.

The Railroad

Will be completed to Granite by the 1st of April, the cars now making regular trips to within half a mile of that point. Considerable anxiety is apparent about where the depot will be, the Granite people praying for a benefit, and land owners protesting loudly, one Jew going into spasms over the matter. The proprietors of the road are sensible, and keep mum, undoubtedly intending to start a new town.

Discovery of Gold.

Considerable prospecting has been made for

engine man at his post, which is at the side of the fly-wheel. To release the brake, the principle in use in the North of England has been adopted—the engine man, directly he takes his stand in the position assigned to him, working by his own weight the lever which disengages the brake. To stop the fly-wheel and to apply the brake, he has, therefore, only to remove his foot.

To the lever, by which the brake is applied to the fly-wheel, Mr. Tildesley has attached an iron bar, through which the draw chain runs, and so soon as the skip reaches the required height at the top of the shaft, the action of the bar locks the fly-wheel in the grip of the brake, and keeps the skip securely suspended at that point. Owing to the use of the open grate, the fire is understood to require renewal only once in about two or three hours. The whole of the apparatus presents a strong contrast to the noisy winding machinery generally adopted in South Staffordshire, and the absence of smoke, together with the apparent impossibility of colliers' lives being sacrificed by the negligence or the oversight of the engine man in working his engine too long whilst men are ascending, seem to us to give to the improvement the importance which, now the New Mines Act is about to be put into operation, should attract the notice of the colliery people of this district. — *London Mining Journal*.

RICH DISCOVERY OF BORAX.—An immense deposit of borax has been discovered in the eastern part of Kern county in the neighborhood of Desert Springs. The borax lies in a stratum of about three feet in thickness and but a few feet beneath the surface of the ground, and is in a perfectly pure state. The discovery was made several weeks ago but has been kept a secret. It has, however, leaked out, and considerable excitement prevails among the Tehachepi people over the great borax mine. Claims are being located and mineral land entered rapidly. — *Southern Californian*.

Another Yellowstone gold excitement is being raised in Montana.

Clarence King's Survey of the Territories.

One of the latest acts of the Forty-second Congress was the appropriation of \$75,000 to continue and reorganize the United States Geological Survey of the Territories under the control of the Department of the Interior. In order to ascertain the character of the change and the nature and amount of work to be done during the coming season, a reporter of the New York *Tribune* called on James T. Gardner, chief geographer of the survey, who is at present in the city, and obtained from him the following facts:

The exploring expedition is to be known as the "U. S. Geological and Geographical Survey of the Territories under the Department of the Interior," and it is proposed to map out the topography and geology of the Rocky Mountain region and the country west of it; to investigate their resources, and distribute the knowledge obtained by means of maps, photographs, and illustrated reports. The work this year will be in Colorado. During last year the Yellowstone park region and the country to the south of it were partially examined with reference to the geological features. Further examination of this region has been postponed because of the difficulty of access to it on account of the hostile Indians infesting it, and because of the trouble and expense attending transportation thither, until the completion of the Northern Pacific Railroad. The scientific corps of the expedition comprises about twenty men, consisting of the chief geologist and his staff, the chief geographer and staff, and the natural history department. The chief geologist, who is also the chief of the survey, is Dr. F. V. Hayden, who has been exploring the country embraced in the survey for about twenty years, sometimes at his own expense, sometimes partly aided by the Government, and, during some periods, solely by Government appropriations. In 1871, the definite mapping out of the geological and natural history features of this far-western region began. The results are comprised in a series of annual reports made to Congress, and in the distribution of the collections of geological, botanical, mineralogical, and natural history specimens, by means of the Smithsonian Institute, to the various educational institutions in the United States. By the recent act of Congress, the investigation of the geographical features of the country is to be added to the work formerly done. Moreover, by the plan as now determined on, it is intended to carry on a connected exploration of the country, instead of, as formerly, a series of disconnected surveys of particular localities.

The principal objects of the scheme are, first, the obtaining of an accurate topographical map of the country; second, the careful mapping of its geology, and, third, the investigation of the connection of these with our mineral and agricultural resources. One gentleman of the party devotes himself almost exclusively to investigating the agricultural resources of the regions surveyed, noting the kind of soil, the meteorological conditions, the existence and prevalence of destructive insects, etc. By means of the Clarence King exploring expedition the Arizona diamond fields fraud was exposed. The story, as told by Dr. Gardner, is an interesting one. The finding of the place which was kept a secret by the originators of the scheme, depended upon the geographical, while the discovery of its fraudulent character was due to the geological knowledge of the region obtained by the survey. Another point in favor of expeditions like these is the following: The coal of the country occurs in a very different kind of rock than the Pennsylvania coal, and it is of the utmost importance to have the coal beds mapped out. It is proposed to start the expedition as soon as the weather will permit. The general plan of the expedition will be to continue its work of exploration and the collection of specimens for five or six months, and to arrange and classify the specimens obtained; to prepare maps of the region traveled over, and to make out the reports during the remainder of the year. The headquarters of the survey are at Washington where there is a building devoted to its purposes. About 15,000 copies of the reports are distributed annually throughout the country by members of Congress, and many photographs of scenery and natural objects are sent to institutions of learning in the United States.

The *Eureka Sentinel* says that the prospect now is that all the furnaces which stopped about the time of the epizootic will be running in less than a fortnight, and, in addition, the Buttercup works are expected to be started soon.

Useful Information.

Transition Signs.

This style of sign is not very common, but it makes a very neat and showy advertisement for all branches of business, it made in good style. The way to make them is, first get the sign board made the dimensions required, with a projecting band or moulding around it, say about one and a half inches deep from the face of the board to the outside edge of the band or moulding; then cut into the band or moulding around the board, from the top to the bottom edges, grooves the width of a hand-saw, one inch apart; then insert strips of tin one inch wide, and long enough to reach from the top to the bottom of the sign board, including the band; thus covering the face of the board. When all are neatly fitted, take them all out, laying them down flat, with the edges close together, and paint on them any work, figure, or design required. Let them remain until perfectly dry, then turn them all over, keeping them in the same order as before, turning them over from right to left. Paint the surface of the board with any letters, picture, or design required. Then paint on the strips of tin, on the reverse side from that previously painted, still another word, or design, and when dry, slide the strips of tin in the same order in which they lay, into the grooves on the sign. The sign is now completed, and has a very magical effect to those passing by, changing from one word or design to another, and makes the very best, cheapest, and most attractive sign that can be got up. It is not expensive, and only requires a little ingenuity to construct one.—*Cabinet Maker.*

A CHEAP PAINT.—We have not much faith in any of the so-called cheap paints recommended for outbuildings. Common whitewash with yellow ochre, or some other mineral substance for giving the required color, may in some instances prevent the decay of wood, and add something to the appearance of the buildings upon which it is used; but white lead and linseed-oil make the cheapest and best paint in the end, although costing a little more at the beginning.

But as a subscriber asks for a recipe for making a cheap paint for outbuildings, we comply with his request by giving one that has considerable popularity among gardeners:

Palverize charcoal in any quantity desired, add a little litharge to a drier, mix with raw linseed-oil, add a little boiled oil when applied. This will make a black paint, but by adding yellow ochre, a peculiar shade of green may be produced. Other mineral substances may be added if desirable.

TESTING GOLD USED IN GILNETS.—P. Gayot proposes for this purpose the use of a solution of chloride of gold or a solution of nitrate of silver. Neither affects at all the genuine gilding, but imitations, when touched with the former solution, show a brown spot, and with the latter, a gray spot. The gilt designs of wall papers are examined by Gayot with chloride of sulphur. One drop of this salt, placed on imitation gold paper, produces a dark brown rim, which does not appear when gold has been used. Thin gold leaves, if placed with chloride of sulphur in closed bottles and well shaken, show no change, but alloys of base metals gradually blacken. If the gold is placed in hermetically closed bottles under a slight aërostatic pressure, it will disappear in a short time and combine with the chlorine to form chloride of gold.

AN UNPLEASANT SUGGESTION.—A POSSIBLE CALAMITY.—The New York World asks: In case of a fire stretching suddenly across Manhattan Island, and then sweeping rapidly toward the Battery, what would become of the people south of where the conflagration originated? Where would they go? How would they get away? Could a sufficient number of steam-boats approach near enough to such a fire to rescue them all? If not, the tragedy of the Fifth Avenue Hotel, fearful as it was, would be but a feeble illustration of a spectacle which the most distant parts of the civilized world would not cease for centuries to remember with horror.

A ROCK CRYSTAL WATCH.—One of the curiosities of the Vienna Exhibition will be a watch made entirely of rock crystal. Many years since, a workman in a French manufactory decided to make a watch, every part of which, the mainspring alone excepted, should be of rock crystal, and after thirty years labor accomplished his task. All the pieces of the watch are fastened by rock crystal screws, and the escapement is most intricate. His widow would never part with it; but when she died, the treasure fell into the hands of a French watchmaker, who intends to exhibit it as a sample of French workmanship, pricing it at \$2,000.

TO DELAY THE "SETTING" OF PLASTER OF PARIS.—In many cases the rapid consolidation of plaster of Paris is a serious inconvenience, but it is said in a French journal that this difficulty in its employment may be remedied by the addition of from two to four per cent. of the root of marsh mallow, finely powdered. With this treatment the plaster, it is stated, will not set for an hour at least.

CARPET MANUFACTURE IN PHILADELPHIA.—The carpet interest in Philadelphia has reached enormous proportions, and is still rapidly increasing. There are about 250 manufactories, which employ, on an average, about 50 operatives each. The number of looms is estimated at 8,000, from which 800,000 yards of ingrain, damask, Venetian, two and three-ply carpets are turned out weekly. The number of yards manufactured annually has averaged 41,600,000. The amount of capital invested is \$3,000,000. The carpets made here have gained the widest and highest celebrity for fine, wearable texture and handsome designs.

A HAPPY THOUGHT.—Willis Williams, of Islesboro, Me., was recently out on the ice hunting seals, when an accidental discharge of his fowling piece wounded him so badly in the thigh that he could not walk. He smeared the dog's face with blood and told him to go home, which the sagacious animal did, and by signs and the blood alarmed the family, who followed him to the place where the young man was lying. The hint may be worth remembering by our friends of the Nimrod persuasion.

MAKING PAPER STICK TO WHITEWASHED WALLS.—Making a sizing of common glue and water, of the consistency of linseed oil, and apply with whitewash or other brush to the wall, taking care to go over every part, and especially top and bottom. Apply the paper in the ordinary way.

STANFORD ECLIPSE.—It is estimated that nearly one-third of the railroads of the United States are under the control of a few individuals in one corporation, called the Pennsylvania Railroad Company, of which Thomas Scott is king.

Good Health.

Hints in Regard to the Eye.

The sculptor Crawford was accustomed all his life time to read lying down. To this, very largely, the physician attributes the loss of his eye. Very soon a cancer formed in the other, which caused his death.

The great historian Prescott lost his eyesight when a student by a bit of bread thrown in sport by a fellow-student at the table. A pair of scissors or a fork thrown in sport or anger, has caused the loss of an eye, which the wealth of the world can not replace. A friend who was very ambitious to finish a set of linen for her brothers, spent almost a winter in the stitching, sitting up often late at night over the work, in which she took great delight. The result was, the nerve of the eye was so injured that she was obliged wholly to give up sewing, knitting and reading, under penalty of becoming perfectly blind.

A young lady, who lived but ten miles by train from school, used to spend the time in studying a certain lesson while she was riding down in the morning. The result was a severe inflammation of the eyes, which disabled her from study for a long time. It is always harmful to the eyes to read in the train, though we may not see the effect so plainly when it happens only occasionally. A steady practice like this, young ladies, may produce even worse results when the system is in a bad state.

Never read by twilight, nor before eating in the morning. This little you gain in time will be doubly lost before life's sundown.

I know a young clergyman who is a remarkably well-bred man, but whose eyes are a perfect deformity. He said he ruined them by reading at night, long and intently, when he was getting his education. He seems to have no control of the lids, which twitch and move in a most grotesque manner. Don't fancy you can do what you please with your eyes, and yet have them serve you faithfully. Take good care of them as you would of gold, for gold can never replace lost eyesight.

A Remedy for Croup.

We have been interested in reading the following statement made to us by an intelligent mother. We give our readers the benefit of it, or at least give them the opportunity to test whether it has any benefit.

A remedy for croup was given me by a sister who heard it from Prof. Brownson, a physiological lecturer since deceased.

"Let a healthy person fill his lungs with pure air, then slowly breathe upon the patient's throat and chest, commencing at the point of the chin, and moving slowly down to the bottom of the wind-pipe. Repeat for a few minutes and it will give relief in cases when all other means fail."

My boy was always subject to croup; came near dying with the rattling noisy kind, at about eleven months old. I saved him with water and ever after prevented a serious attack by watchfulness and water. But when three years old, I let him play in the brook one warm rainy day, and he took a severe cold and had a bad kind of croup, the first and last time he ever had it. In spite of all I could do he grew constantly worse until he could only gasp and breathe with his head thrown back. We thought his last moments had come, when I thought of, and tried Brownson's remedy for a minute. When I stopped he looked up and said: "Do so again, mother, do," though he could not speak when I began. You may be assured that I did so again, and I believe it saved his life.—*Lance of Life.*

A NEW AND DANGEROUS POISON.—A Baltimore physician says that the new medicinal compound, known as "xylo," is now being largely used in that city as a means to facilitate robbery and murder. He says that a person may be rendered powerless by its use so that the burglar can go through the house and take all he wants. If necessity require it, the burglar can xylo his victim out of this world into the spirit land in an incredibly short space of time. The mode of application is by mixing it with the feathers in a pillow, and when the warmth of the head is applied to it, it gives off vapors similar in effect to the fumes of charcoal, and the person using it is found dead in the morning, which gives the monsters who apply the drug ample opportunity to possess themselves of the property of their victims, and to dispose of their remains.

He says the drug was tried upon himself some time ago by a German Jew, who invited him to sleep in his house. He escaped his foul designs, by obtaining knowledge of his intentions and manner of proceeding, by trifling circumstances, the details of which are not given. He thinks that many of the late cases of "mysterious disappearance" may reasonably be attributable to the cause.

FAT AND LEAN.—Meat eaters and vegetarians show in their persons the effects of the diet. The first has the most brain force and nervous energy. A mixed food of animal and vegetable rations develops the highest intellectual powers. A strictly vegetable living ordinarily gives a fair complexion, and amiability and extreme pugnacity when the vegetarian's views in regard to that one engrossing thought of his life are discussed. They are annual meeting reformers, without ever setting the river on fire. Arabs are a sober, frugal race, rather slender, not tall, conscientious and contentious on religious subjects. They largely subsist on rice, pulse, milk and kei-uac, something similar to whipped cream, through a vast region of an arid country where they are indigenous. They are not destitute of mutton, goats, camels and game; but they manifest no disposition to feed upon meats, as is necessary in temperate zones or in high northern latitudes. An intellectual man, one of their kindred, who rises to distinction by the grandness of his mental status, is exceedingly rare. The beer and ale drinkers expand and grow fat, but they are not much given to profound researches in science.

ARRANGEMENT OF HOUSES.—Much in the way of good health depends on the proper arrangement of our houses.—The American Builder says: "Do not arrange your house so as to violate God's first command. Give it many windows, and then, O housewife, keep your blinds open during the day and your curtains drawn aside. If you let the sun in freely, it may fade your carpets, but if you do not it will be sure to cause ill health to the mother and children. The sun is a good physician. He has never had due credit for his curative qualities—for the bright eyes and rosy cheeks that come from his healing bath. Do you know how puny is the growth of a potato vine along the darkened cellar wall? Such is the health of human beings living where the sun is intercepted by the window's drapery. So dark wall-paper is not only gloomy, but it is physically unwholesome. Let in the sun, for with it comes cheerfulness and strength! A dark room is an enemy of good health, good temper and good morals."

IS INEBRIETY ON THE INCREASE?—In a late number of the *Contemporary Review*, Herbert Spencer combats the idea that inebriety is on the increase. He describes the time when men took drugs to increase their desire for wine; when glasses were so shaped that they had to be held until emptied; when a man was reckoned as a "two-bottle man," a "three-bottle man," etc.; and when (Mr. Spencer might have added) one of the first of Scottish nobles employed a domestic whose sole duty it was to sit under the table and loosen the neck-cloths of the guests as they fell from their chairs, in order that they might not suffocate in their drunken sleep. Intoxication used to be a mark of honor. It is now a disgrace. Education has driven the evil from one class after another. It is now almost exclusively confined to the lowest. As Mr. Spencer says, the remedy for it in England is not a "Maine-law," but the introduction of the education that has banished it elsewhere.

BETTER THAN MEDICINE.—Dr. Hall says the best medicine in the world, more efficient in the cure of disease than all the potencies of the materia medica, are warmth, rest, cleanliness and pure air. Some persons make it a virtue to brave disease, "to keep up" as long as they can move a foot or crook a finger, and it sometimes succeeds; but in others, the powers of life are thereby so completely exhausted that the system has lost ability to recuperate, and typhoid fever sets in and carries the patient to a premature grave. Whenever walking, or work is an effort, a warm bed and cool room are the very first indispensables to a sure and speedy recovery. Instinct leads all beasts and birds to quittance and rest the very moment disease or wounds assail the system.

TOBACCO-SMOKING.—A German physiologist has discovered that tobacco-smoking by the boys "interferes with the molecular changes coincident with the development of tissues, and makes the blood corpuscles oval and irregular at the edge." Any parent can thus ascertain if his boy smokes by merely taking out a handful of his blood corpuscles and observing their edges.

MISCELLANEOUS.

German Prejudice Against Potatoes.

There exists in Germany a decided prejudice against potatoes, because they are composed of three-fourths water, with but ten to fifteen per cent. starch contained in indigestible cells. The French, who make a perfect science of the whole business of nourishment and cookery, rarely eat potatoes except occasionally tried for the second breakfast. They consume beans more than any other vegetables and with reason, for dried beans contain twenty-two per cent. albumen and fifty of starch, and the common lentile twenty-six per cent. of albumen and fifty-six of starch. In the monasteries of France and Italy great quantities of beans are used, especially during the Lenten season. German naturalists are now searching all over the world for a substitute for potatoes, and this is believed to have been found in China in the "dioscorea japonica," which endures the greatest cold and is more nourishing and better flavored than the potato. In the Museum of Natural History at Paris, a specimen three feet long and weighing three pounds was exhibited.

Several German writers upon races, predict that nations, far from improving, will deteriorate both in physical and mental characteristics, if potatoes become a principal article of diet. The celebrated Carl Voigt says "that the nourishing potato does not restore the wasted tissues, but makes our proletariats physically and mentally weak!" The Holland physiologist Mulder gives the same judgment, when he declares "that the excessive use of potatoes among the poorer classes, and coffee and tea by the higher ranks, is the cause of the indolence of nations." Leidenfrost maintains that the revolutions of the last three centuries have been caused by the changed nourishment. In former days, the lowest workmen ate more flesh than now, when the cheap potato forms his principal subsistence, but gives him no muscular or nervous strength.

Roast Turkey.

Select a fine, plump, yellow skinned turkey, weighing from ten to twelve pounds. Examine it thoroughly to see that all the pin feathers are taken out; hold it over a blaze to singe any fine hairs that may remain; wash it thoroughly inside and out, and rub it over with salt. Take the gizzard, heart, and liver, put them in cold water, and let them boil until tender. When done, chop them very fine. Take stale bread, or the large Boston crackers, and grate or chop them. Add salt, pepper, and some sweet herb if liked, to the bread crumbs; after which beat two eggs with which to moisten the crumbs; add and mix thoroughly with this the chopped "inward," not forgetting to put in salt and butter. Fill the inside of the turkey with the dressing, taking care that the neck or crop is made to look plump, and sew the openings, drawing the sides tightly together. Then rub a little butter over your turkey, and lay it upon the grate of your pan. Cover the bottom of the pan with boiling water. After a half hour have the turkey by pouring over it the gravy that has begun to form in the pan. Repeat the basting once in about fifteen minutes. In an oven of average temperature a twelve-pound turkey will require at least three hours; but every oven has its own way of baking, and the cook must be governed by it.

Roast goose is to be prepared in the same manner as the turkey. The dressing should be made of mashed potatoes, seasoned with salt, pepper and sage, or onions, if according to the taste of the family. Make giblet sauce by boiling the "inwards" until very tender, chopping them fine, and adding them to a gravy made by using the liquor in which they were boiled thickened with flour, and to which has been added one ounce of butter, and pepper and salt to suit the taste.

DANGEROUS DIETS.—The frequent failure of the potato crop in England and Ireland is likely to bring about an epidemic of scurvy, unless the public can be better informed of the requirements of an antiscorbutic diet. The fact therefore, cannot be too widely made known, in fact, whether we are suffering under the failure of this important crop or not, that peas, pudding, haricot beans and boiled rice, which have been suggested as substitutes for potatoes, will not prevent the occurrence of scurvy. In the absence of the potato, an excellent antiscorbutic, fresh green vegetables or fruits will be requisite, or the health will fail, even though fresh meat be taken. Amongst the vegetable material which may be used, are the various forms of cabbage, lettuce, oranges, lemons, onions, mustard, cress, dandelion and sorrel. The experience of the crews of vessels on long voyages has shown, over and over again, the uselessness of the pea and bean tribe in preventing scurvy.

TO MAKE POP CORN BALLS.—While popping your corn put some syrup on the stove, the nicer the better, and boil it down quite thick. Put your corn while hot in a dish pan, or any large vessel convenient, pour the syrup over it and stir it well with a spoon. It only needs enough to make the corn stick together. Butter your fingers and make up the balls quickly any size you wish. Lay on a plate until cool, and they are nice.

W. S. EWER..... SENIOR EDITOR

DEWEY & CO., Publishers.

A. T. DEWEY, GEO. H. STRONG,
W. S. EWER, JNO. L. BOONF.

Office, No. 338 Montgomery St., S. E. Corner of California St., diagonally across from Wells, Fargo & Co.'s.

SUBSCRIPTIONS payable in advance—For one year, \$4; six months, \$2.50; three months, \$1.25. Clubs of ten names or more, \$3 each per annum. \$5. in advance. will pay for 1½ year. Remittances by registered letters or P. O. orders at our risk.

Quicksilver.

In north-western Guatemala there is an intermittent spring of quicksilver. The stream is about the size of a quill; not always uniform. The cause of the flow is no doubt volcanic heat. An active volcano is in sight and hot water springs abound. A dense chapparal shuts out access to animals; but native men and women fill cane stocks with mercury, and thus carry it to the city of Guatemala.

That fine country is now being opened to commerce by railways, and soon we may expect large supplies from that State.

The last news from Sinaloa, Mexico, announces a shower of mercury covering several fields and people were represented as gathering the fluid metal, to preserve as memorials, and some find it in quantity enough to speak of the profits of the quicksilver crop.

THE NEW REVENUE CUTTER.—The new Revenue Cutter Oliver Wolcott was launched on Thursday morning last from North's Ways on the Portrero. She was built by Dickey Bros. after a model of their own design, under the supervision of Captain White, of the Revenue Service. She is 270 tons register, 130 feet over all in length, 22 feet beam, and 9 feet 2 inches in the hold, and has a 300-horse power engine, which was built at the Bidson Iron Works. We shall have a more extended description of this California built steamer when her trial trip is made.

THE STEEKEN RIVER. A party of French miners has been organized in this city to proceed to Steeken River country (British Columbia), for the purpose of working the immensely rich mines reported to have been discovered there.

Borax—How It is Obtained.

Boracic acid is by no means very profusely distributed over the earth's surface, and borate of lime in particular, has until lately only been found near the celebrated nitrate of soda deposits of Iquiqui in South America. Recently, however, large masses of borate of lime have been discovered in Churchill, Esmeralda and other counties in Nevada. The mineral found in Nevada is the same as that found in South America. It is not true borate of lime but a combination of borate of soda and borate of lime. A recent analysis of this substance by F. Gutzkow gave in round numbers

Boracic Acid.....42
Soda.....8
Lime.....13
Water.....37
Total.....100

There appears to be some difference in the impurities found with it. In Nevada this appears to be principally clay, while in South America, gypsum is always more or less found intermixed with it. Owing to these impurities some difficulty has been experienced in working the mineral in England and France. The expectation that South American borate of lime would be a prolific source of borax has failed, from the circumstance that the shipments from Iquiqui turned out to be of a very unequal nature as to quality, which with the difficulty of ascertaining the true proportion of boracic acid by an easy assay, has rather demoralized the market for the substance in question.

The Process Now Used for Obtaining it

In this country consists of a concentrating operation in which, by an enormous loss in substance, the borate of lime is freed from its impurities. Then it is hoiled with a solution of carbonate of soda and the solutions obtained worked for a crude borax to be refined afterwards by re-crystallization. This process has several important drawbacks. In the first place the high price of soda on this Coast interferes seriously with the operation. Although the State of Nevada possesses large deposits of crude soda, the high rates of transportation enhance its value to such a degree that it is almost as advantageous to employ the English sal-soda, which is, moreover, a much purer article. Furthermore, the decomposition of borate of lime is not complete with the use of soda, and the residue will always contain some undecomposed mineral, unless a very large quantity of water is used. As the borate of lime is not insoluble in water, it is possible to extract, by water alone, all traces of the mineral; but on a large scale this is, of course, not possible. In the third place the clay mixed with the mineral and the carbonate of lime formed by the soda makes the residue extremely bulky. It takes considerable time to make it settle into a pulp of some reasonable thickness. Therefore several washings are required to wash out the absorbed borax solution; thus yielding weak solutions which have to be worked up, and concentrated.

Some New Experiments in Freeing Borax from its Natural Impurities.

Lately Mr. F. Gutzkow of this city turned his attention to the subject and invented a process, which he has had patented and which depends upon the volatilization of boracic acid by water vapors, a principle which Nature itself proves correct by furnishing in that way, all the boracic acid manufactured in Tucumán. At the last meeting of the California Academy of Sciences Mr. Gutzkow described his process in a small way, with appropriate apparatus, and demonstrated the feasibility of his plan. He has discovered that volatilization can be made complete, that is, that a given quantity of boracic acid can be completely volatilized by steam alone.

The plainest experiment, and that which laid the foundation of his process is this: To melt, in a platinum crucible, some boracic acid into a glaze; weigh the crucible with contents, and then conduct steam by a brass tube into the crucible, while the latter is heated to redness. By weighing from time to time, the progress of the volatilization may be observed. After continuing the experiment for two hours—more or less—the crucible will be found entirely empty. By other experiments, in which he suspended a weighed platinum wire on which was a head of boracic acid, in an iron gas pipe, steam of different temperatures being conducted through that apparatus, he showed that the rapidity of the volatilization depended entirely upon the temperature of the steam. Steam of 212° F. is not capable of removing more than

traces, unless the reaction is allowed to continue for a long time. If the gas pipe surrounding the boracic acid head is, however, heated to redness the volatilization is most rapid.

The rather surprising fact that steam of 212° F. has so little power for the purpose required, caused Mr. Gutzkow to experiment on some statements of Henry Rose, the celebrated chemist, to whom we are mostly indebted for our knowledge of the element boron and its combinations. Rose states that it is not possible to concentrate a solution containing free borax without loss of substance. This was found correct when the solution is evaporated in an open dish; but not so when the concentration takes place in a glass flask. On concentrating an already quite concentrated solution of boracic acid in a glass flask over a moderate fire, Mr. Gutzkow could never condense more boracic acid than the mechanical carrying off by the vapor would account for;—that is, a trace.

In an open dish, however, in the progress of concentration, a ring of boracic acid separates on the dish, which boracic acid is heated more than the solution, and is exposed to the action of the steam rising from the liquid. In that case a volatilization takes place.

Having found out that superheated steam is much more powerful in carrying off boracic acid than steam of 212° F., it was easy to conclude that the condensation of the volatilized boracic acid could not present great difficulties. The boracic acid volatilized in the apparatus spoken of before—that is, in a heated iron pipe—was found condensed in the colder portion of the pipe. By regulating the length and temperature of the pipe the fact presented itself that the steam can be deprived almost entirely of its percentage of boracic acid. With these facts in his mind the reader can easily understand

Mr. Gutzkow's Process.

Which is as follows: The borax of lime can be used as formed in the borax marshes, or more or less prepared, as is done when it has to be transported for any distance. It is placed in a lead-lined, shallow pan, covered with half the weight of water, and allowed to stand for a day or longer, in order to allow lumps to dissolve. Then, from one-quarter to one-half the weight of sulphuric acid is added, and the whole well stirred into a stiff pulp, which is taken out and thrown into a heap. After some days the mass becomes hard, as the gypsum formed commences to set. The mass is then ready for distilling with steam. This is done in an iron retort with an arrangement for heating it. A gas pipe, 12 feet by 1½ feet will answer all purposes. It should stand in an upright position, in order to facilitate the charging and discharging, and also to cause an equal action of the steam. When the pipe is sufficiently heated so that no condensation of steam will take place, steam is admitted. It becomes superheated within the retort, and carries along the boracic acid, leaving a porous mass of gypsum, etc., which, when the operation is continued sufficiently long, will be found entirely free from boracic acid. It has been before mentioned that the rapidity of the operation depends upon the heat employed. If the temperature of the retort is nearly to a red heat, from one to two hours will suffice to finish the operation in the lower part of the retort. If the temperature of the retort is only, say 400° F., which is very easily reached within the retort, about four hours will be required.

The details of the apparatus which allows a continuous working and by withdrawing only half the contents every four hours allows the mass to be exposed twice as long to the action of the steam, we will omit and merely describe the process.

The steam which leaves the retort is highly charged with boracic acid. It can be made to absorb not less than the fourth part of its weight of the hydrated boracic acid. From the retort it passes into a brick or lead-lined wooden chamber where most of the hydrate boracic acid will be deposited. Then it passes through another chamber, or better, a long fine provided with metallic gratings, before it escapes into the atmosphere. A worm condenser can be used and a strong solution of boracic acid will result. It may also pass through a coil of lead or other metal which permits the utilization of the waste heat. There are numerous devices to remove, by partially condensing, the last traces of boracic acid, if desired.

Most of the boracic acid is, however, found in the first chamber as hydrate boracic acid and can from time to time be removed. It can easily be melted in a glaze, taking care to condense the boracic acid, during melting, and is absolutely pure. In the state as found in the chamber it may contain a little sulphuric acid but by the admixture of some coke or charcoal with the top layer in the retort, the sulphuric acid may be easily converted into sulphuric acid gas which escapes uncondensed from the chamber. There is no substance present to interfere with the purity of the product obtained. In a mechanical way nothing can go over as the mass within the retort becomes all glazed over by boracic acid.

The Advantages Claimed for the Process

Are, that with very little labor, in one single and short operation the mineral can be extracted. There are no rich residues left to be worked over, nor liquors to be concentrated, which makes the lixiviating process so complicated. Besides, the boracic acid, and particularly the boracic acid glass, can bear the high cost of transportation from the borax marshes to the market much better than the borax or borate of lime. To bring one pound of borax

from the marshes to the market, that is, in New York or European ports, costs now from six to seven cents. To transport the molten boracic acid which gives three pounds of borax nearly to the pound, would reduce the cost of one pound of borax by two thirds. Mr. Gutzkow's explanation of his process was very interesting. We understand that works to be conducted on this plan will shortly be erected in Nevada, when we will be able to give some details of practical operations.

The Gold Note Banking System.

The necessity of having some medium besides gold, wherewith to facilitate business, has been recognized by the business world, so long, that it is almost unnecessary to expatiate on it. The increase in the production of the precious metals never has kept pace with the increase in the volume of business, and never will. But money of some kind or other is as necessary to the conducting of business operations as is natural or artificial irrigation to the production of crops, or as is a full and healthful flow of blood through its accustomed channels to the vivifying of the human body. Now, the contraction of the volume of specie by export, or its inadequacy to the wants of an increasing business, must result in great calamities to the whole of the business community. The natural results are the cheapening of all commodities, and were this through any cause to occur suddenly, it would be found most disastrous to the business community.

The value of the merchant's stock in California would be depreciated in proportion to the rise in gold, while his liabilities, remaining the same in nominal amount, would be really increased as much as his stock was depreciated. To illustrate: let gold universally rise 25 per cent., with a volume of business increased proportionately, and let this advance be continued for a year without there being any expansion in the way of currency or other paper money.

Then the stock a merchant purchased previously for \$100,000, would in accord with the inexorable laws of supply and demand, have to be sold for \$75,000, while it would cost him \$125,000 to purchase gold to pay his creditor. That would be a loss of \$50,000 or 50 per cent. The gold note system is the only one capable of supplying a deficiency of the circulating medium, where as in California, currency is not a legal tender. Without it money would now be even tighter in this State than it is. We shall on a future occasion point out the difference between the gold note and the currency system, now contenting ourselves with giving a resume of February's statements, by both our gold-note banks, the resources of the

First National Gold Bank

Of San Francisco on the 28th day of February, 1873, was \$2,574,056.25, of which \$1,257,220.67 consisted of loans and discounts, \$800,000 of U. S. bonds and \$451,573.03 of coin and gold checks on other banks. Its capital stock was \$1,500,000, and National Bank circulation outstanding \$528,720. The resources of the

National Gold Bank and Trust Company

Of San Francisco, on the same date, were \$3,599,961.77, of which \$1,955,704.59 consisted of loans and discounts, \$750,000 of U. S. bonds, and \$351,794.46 of coin. Its capital stock was \$1,000,000, and its National Bank circulation outstanding \$595,620.

DAMASCUS BLADES. — It has long been a matter of comment among unscientific persons that steel made by the rudest processes and under the greatest disadvantages, apparently, should yet be so highly estimated. So much has been said in books of travel and works of fiction (appropriately classed together, by the way), about the superiority of "Damascus blades," "Malay cresces," "Toledo rapiers" and the like, that it is not to be wondered at that an exaggerated impression is the result. None of these kinds of steel compare at all favorably with fine grades of Sheffield manufacture. Their good qualities, in every case, are owing to the purity of the ores and fuel employed—usually perfectly pure magnesian and charcoal. In days gone by they led all rivals, now, with our perfected refining processes and improved machinery, we wonder that our ancestors found so much to admire in these far-famed brands. We cannot afford to use charcoal made from rare woods nor is it found practicable to waste so much labor on so small produce; but from common pig metal the keenest steel for surgical instruments is made, and that too in almost unlimited quantity. The world does move.

Underground Irrigation.

This is a subject every day commanding more and more the attention of amateur culturists as well as the general farmer. It is a means by which our gardens can be efficiently irrigated and made to present a perpetual and unvarying growth of plants, vegetables and fruits, and our lawns and parks a perpetual green, and this without the unsightly and inconvenient process of surface irrigation, with its malarious influences.

In our illustration we present a view of a new invention and its application to the purposes of underground irrigation. It consists of pipes of peculiar construction and their arrangement in such manner as to secure the purposes claimed and desired. The inventor in his description of his appliances, and in his application for a patent, says:

"This is an invention for the conduct of water underground long distances without waste, for the purpose of irrigating the soil to promote the growth of plants, trees and growing crops.

The lower part of the pipe being whole or tight, no water can escape until the pipes are half full, if laid level. The pressure of the water being equal it will issue from the cuts or holes in the upper half in equal quantity at all points. The large box, No. 1, is the supply receiver, to be placed under a pump or hydrant, receiving the conducting pipe at A, which conducts the water in any direction in a straight line; where the direction is to be changed the pipe enters a small box-well, No. 2, which receives similar pipe running in other directions. If the ground is inclining and we wish to extend our pipes, and at the same time retain the same depth in the ground, we are forced to change our level. This is accomplished as represented by box-well No. 3. The pipes enter this on the same level, letting the water out on the other side into pipes on a lower level.

The water in the pipes is controlled and directed by means of valves covering the ends of the pipes in the wells, No. 2, 3 and 4.

No. 4 represents a box-well for conducting water from the upper terrace to a lower terrace on terraced grounds. The pipe enters at O, on the upper terrace, letting the water into the pipes laid on the terrace below, at B, controlled by valves, reached by opening door, F. The wells are made deeper than the pipes, to receive and hold any sediment contained in the water, and which may be removed when necessary.

These pipes will also answer the purpose of drainage, draining the soil above the level of the pipes of any excess of water during the winter season. By simply removing the plugs in the ends of the pipes we reverse this operation and they become drainage pipes. As the pipes become exhausted, water will enter them at the points where it is forced out by pressure in irrigation, and as it flows out at the ends it can be conducted into drains or sewers. This operation will leave the soil above the level of the pipes in a fine condition for the rapid and healthy growth of plants. The pressure of the water in the wells coming from the supply pipe keeps the valves closed, they can be opened by the operator by means of a rod attached to them, carrying the whole volume of water in any direction."

VALUE OF HUMAN LABOR.—Some idea of the pecuniary value of human labor may be had by noticing the enhancement acquired by iron as it passes through the hands of its skillful manipulators. Crude pig metal at (say) 20 per lb. becomes worth \$500 per lb. in the form of the finest hair springs. The cheapest metal thus becomes far more valuable than gold, through the application of human skill. The one value is 25,000 times that of the other. This is a startling leap, but we can take in the truth better by following the metal through its different stages of refinement—refined pig, bar iron, terne plate, shear steel, penknife metal, razor steel and surgical instrument steel, etc.—and so accustom ourselves to the steady gain.

And then the tenuity of the thread on which the enormous value of the finest product depends! Suppose that, while this pound of metal more precious than gold was in the melted state, a careless workman should drop a match or a pinch of sulphur upon it. The mere addition of so minute a quantity of an injurious element would destroy at once the worth of the whole.

The Spectroscope and the Stars.

The fourth of the series of lectures on the spectroscopy, in course of delivery by Prof. Neri at the hall of St. Ignatius college, was listened to by a large and attentive audience, and illustrated by numerous beautiful and instructive experiments by means of diagrams projected on a screen by the electric light.

The previous lectures having fully explained the principles and powers of this new and wonderful instrument, the present one was devoted to a consideration of its application and results to solar chemistry.

What the Spectroscope Tells us of the Sun and Stars.

Heretofore man's only knowledge of the character of the heavenly bodies has been derived from falling meteors; but the testimony which they bring is very uncertain. But the spectroscopy, besides revealing an intimate knowledge of the character and composition of terrestrial substances, has also been found competent to reveal the character, elements and physical constitution of all heavenly bodies, which emit light sufficient to render them visible by means of any astronomical instrument. That there is no mistake about this—that the spectroscopy is no uncertain teacher—was distinctly shown by a series of interesting and thoroughly convincing experiments and demonstrations.

In addition to receiving and taking in the light of the sun, it also seizes upon the smallest ray of light, from the dimmest star, comet or nebula, and, by a peculiar arrangement of

bright, and the term "lines" in reference to those which are dark.

In examining the spectrum of the sun we see both dark lines and bright bands. Some 3,000 of the former, besides many of the latter are observed upon the solar spectrum; but we are not to infer from that fact that there are so large a number of different elements in the sun; for a single element often gives several bands or lines, as the case may be. For instance—iron gives some 600 lines, all of which are due to that single element.

The study of these lines and bands upon the various spectra is far from being completed. Many lines which at first were supposed to be single, by improved instruments are now found to be double, and often a large number of very small lines is found to make up what was once supposed to be one very broad line.

A Mystery.

When we examine metals or other elements in the laboratory, by means of the spectroscopy, we invariably obtain bright lines on the spectrum. Those lines always occupy a certain place, never varying their position. Thus by a series of experiments, the place on the spectrum for the lines of each of the different elements has been definitely fixed, no one ever interfering with or occupying the place of another. These facts were learned early in the history of the spectroscopy.

Subsequently, when Fraunhofer turned his spectroscopy to the sun, and began to examine the solar spectrum, he found a large number of dark lines. He at once commenced a study of those lines—what were they? Could they be the lines of earthly elements? No, for they were dark; while the lines of the earthly elements, as examined in the laboratory, were

AIKEN'S UNDERGROUND IRRIGATING APPARATUS.

prisms, disposes or spreads out that ray so as to bring it within ready examination, and separates its light into a spectrum of prismatic colors; and if that ray is from a highly heated vapor or an incandescent body giving out highly heated vapors, it projects upon that spectrum, as a background, certain dark or bright lines, or bands, as they are sometimes called, which lines determine the character and constitution of the body under examination,—one or more lines appearing in a certain position for every different element whose light is thrown upon the spectrum.

If the spectrum we obtain is a continuous one, merely spread out like the colors of the rainbow and without any bright or dark lines across it, we know that the body emitting the light is either an incandescent solid or liquid one, and not a body of incandescent vapor or even one giving off such vapor.

If bright lines appear across the spectrum we know that the body is composed of highly heated vapor, and that the lines (according to their places on the spectrum) represent some given element.

If instead of bright we have dark lines, we know that we are examining a body capable of absorbing certain rays of light, thus giving rise to what is called an absorption spectrum—the dark lines being simply shadows of the various elements which they represent.

The different characters of the spectra thus determine certain general characteristics of the bodies submitted to their test. The bright lines upon the spectra tell us, by their numbers, position, relative brightness and color, how many different substances or elements there are in a luminous body we are examining. By comparing these lines with the spectra which we obtain from earthly elements, we are able to name them as far as they correspond.

Of earthly elements found in the sun we have already discovered iron, titanium, calcium, magnesium, nickel, cobalt, chromium, barium, sodium, copper, zinc, hydrogen, in large quantities, aluminum, selenium, cesium, strontium, and probably iridium.

No indications have yet been found of gold, silver, mercury, platinum, lead or tin in the sun.

In speaking of the lines or bands upon the spectrum, the term "band" is generally employed, when reference is made to those which are

bright. Further examination, however, showed that many of these dark lines corresponded exactly with the bright lines of the metals. Still another mystery! How was this? Here was a mystery indeed. Was the spectroscopy, after all, to teach us only an uncertain lesson?

Scientists in continuing the studies of these lines, discovered that it was impossible to pass through an incandescent vapor of any substance, the rays of light which that substance is capable of emitting. If now we employ the spectroscopy to project the spectrum of sodium, on a screen, with the sodium flame or vapor intervening, we shall have a black band on the spectrum in the place of the bright sodium line, which the sodium flame alone would give—this black line being in reality a shadow cast by the incandescent sodium, in the white light which we are analysing, in consequence of its passage through the sodium vapors in the flame.

This discovery made by Fraunhofer proved one of the most important in connection with the history of this instrument—for continued and multiplied experiments in this direction finally led to a full explanation of the

Mystery of the Dark Lines on the Solar Spectrum

And proved that those dark lines represented elements corresponding to the bright lines observed in the laboratory. The lines of the different elements appeared dark, when coming from the sun, because its light had to pass through the incandescent vapors, of such elements, thus projecting a shadow instead of a bright line upon the spectrum. Thenceforward man has possessed an instrument as sure in its results of the analysis of the sun or any other heavenly body, as is the crucible or other instruments applied to ordinary analysis in the laboratory.

In illustration of the phenomena of absorption, whereby the dark lines are made to appear on the solar spectrum, the Professor gave some very interesting experiments showing the

Philosophy of Different Colors in Glass,

Or other media through which light can but imperfectly pass.

A red glass intercepted all but the red rays; a yellow all but the yellow rays, etc. This was proven by first throwing a spectrum of all the rays from a luminous substance upon the screen, and then throwing upon the screen only such rays from the same substance as would pass

through a red or yellow glass. In the latter case the spectrum of each transmitted light would show, strongly, only the light corresponding to the color of the glass, or other media, with a very small amount of some complementary color, the transmission of which was due simply to imperfections in the coloring matter of the glass. This experiment shows that colored glass does not color the rays of the sun, but merely stops all but the rays corresponding to the color of the glass employed.

This, like each of the previous lectures, was illustrated by numerous experiments and diagrams thrown upon the screen by means of the electric light, and added largely to the interest of what was said, by making almost everything perfectly comprehensible to the eye as well as the understanding. The necessary absence of such diagrams from our report will not admit of anything like justice being done to the subject or the lecture. Professor Neri is peculiarly happy in his manner of treating a scientific subject before a mixed audience; which fact, with the extensive philosophical apparatus, at his command, enables him to keep up the interest of his hearers, make everything clear and well understood and withal present a most enjoyable treat of what is usually, on such occasions, a dry and uninteresting detail of philosophical facts. The fifth and concluding lecture of the season will be given on Thursday evening, the 24th inst.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

IMPROVEMENT IN CHIMNEYS.—J. Browell,

S. F., Cal. This invention relates to that class of chimneys or flues for houses, in which two pipes, an inner and an outer one, are used. Mr. Browell's improvements consist, first in the employment of earthenware pipes or tubes for the inner one instead of sheet iron, as heretofore constructed, and secondly in a novel arrangement of stay rods and supports for holding the chimney in its place, no matter how many joints or sections it is composed of. The patent covers a very nice arrangement for a chimney.

CHANNELING AND EDGING TOOL.—Louis

Bauer, S. F., Cal. Mr. Bauer patents a combined channeling and edging tool for leather workers, its object being to provide a tool which will at one operation trim the edge of a piece of leather and cut an angular channel in the leather near the edge, in which the stitches of a seam are bedded and protected.

PUMP.—Ira D. Cross, Petaluma, Cal.

In this pump one pipe full of water is made to balance another pipe full, so that no matter how high the water is to be raised, the two balancing pipes are carried up to the point

where the water is to be discharged. The two pipes are so arranged that by giving them an alternate motion up and down, they take in water at the bottom and discharge it at the top. Thus it will be seen that as the pipes balance each other the operator has to lift only the amount of water that is discharged at each stroke. The patent covers a peculiar construction of the cylinder, piston, piston-rod and inlet-pipe at the bottom of the well.

WATER WHEEL.—N. J. Coleman, Railroad

Flat, Cal. This invention relates to that class of water wheels which is peculiar to California, the "hurdy gurdy" wheel, and it consists in a novel arrangement of the buckets, whereby the water is made to exert its force upon the full length of the bucket, and by which the power is not lost by the centrifugal force caused by the high velocity of the wheel which in ordinary water-wheels reduces the power of the water to the result of its first impact upon the buckets.

PRINTERS' LEAD RACK.—O. A. Dearing, S.F.,

Cal. This invention will be appreciated by printers—job-printers, especially. It consists of a rack or case having graduated pigeon holes, in which the different lengths of printers' leads are kept separated. The rack is provided with a scale, which serves to aid the compositor in determining the length of each lead, in order that he may readily place it in its proper pigeon-hole. Mr. Dearing is the inventor of quite a number of devices for facilitating the work of compositors. He will have his reward.

CYLINDER WAGON.—George Coffee and William

M. Bernard, Dixon, Cal. This invention relates to a one-wheeled or unicycle wagon. The wagon is not intended for a pleasure vehicle, nor would it answer in a very satisfactory manner as a trotting sulky, but as a wagon suited for doing heavy farm work or as a road wagon it would seem to be quite convenient. It consists of a single broad wheel or drum having an axle (or shaft) passing through its center. The pole or tongue is attached to the opposite ends of this axle or shaft so that the pull upon it causes the drum to revolve. The bed is placed upon ways or slides inside of the drum so that as the drum revolves the bed will keep at the lowest part of the circular ways by sliding upon them. This wagon will also answer as a land roller and for various other farm purposes.

The Cerro Gordo Mines.

These mines, from their immense productive-ness and the great trade they have built up for Los Angeles, and which is now being diverted to this place, have become widely known and celebrated, while yet very little information of an authentic and definite character has been published in regard to them. Since travel and trade to and from them has begun to take this channel, and our business relations with them have commenced to assume an intimate character, we have been at some pains, by inquiry from well informed parties, to collect such facts as may afford to the people of this valley some idea of the extensive market and other sources of trade these mines will afford and which no other section of the State can compete for, unless under circumstances of great disadvantage.

The Mining Camp

Of Cerro Gordo is situated in the Inyo mountains, Inyo county, California, about eight miles east of the northern extremity of Owens' Lake. The Inyo mountains are parallel to the Sierra Nevada, from which they are separated by the long and wide depression occupied by Owens' Lake and the river and valley of the same name. The location, defined with precision according to the public surveys, is in Township 16, South Range 38 East of Mt. Diablo base and Meridian. The town contains somewhere between ten and twelve hundred inhabitants, is built in a depression of the mountains, about six thousand feet above the sea level, and the mines are mostly in and near it.

These Mines Were Discovered

Not long after the great Washoe excitement which led to extensive explorations of the eastern slope of the Sierras, but they were little worked until six or seven years ago. Their present state of development has not been affected by outside capital but has been done by the miners themselves with the produce of the mines. All the principal owners and men who are identified with them, like Belshaw, Beaudry and others, and the Swansea Company, have commenced with very limited means and their present wealth has been created from the proceeds of the mines. The importance of this mining locality can hardly be overestimated. There is no doubt that at this day there would have been as large a population collected about them and as much capital invested in their vicinity as there is at Virginia City and Gold Hill, had they had the same direct and easy means of communication with the coast. The only outlet for their bullion and channel for the receipt of supplies, was the circuitous and almost impassable route via Los Angeles. But this serious drawback is now being obviated by the advance of the S. P. R., and the opening of a wagon road from this place via Tehachapi pass, the advantage of which will be seen by a glance at the map. The mines, which are numerous and extensive, are of argentiferous galena, rich and easily worked. Wood is abundant, and water from the want of which great inconveniences suffered at present, may and soon will be supplied in ample quantity. There are some fine agricultural lands within a distance of ten or twelve miles, in the Owens' River Valley, and plenty of salt in Saline Valley, and other resources and advantages too numerous to mention.

The ores are chiefly a species of sulphides, galenites and antimonial galena, all rich in silver.

The Principal Lodes,

In the vicinity of Cerro Gordo are the "Santa Maria," the first mine worked in the district; the "Omega," owned by the Swansea Co., which furnishes nearly all the ore smelted in the furnace of that Company located near the lake, at the village of Swansea where a large share of the smelting is done; the "Carmen Lode," belonging to a number of practical miners, who work it themselves and sell the ore; the "Jefferson Lode," and the famous "Union Lode," belonging to Belshaw and Beaudry, which is extremely rich in silver, furnishing the ore for two furnaces that smelt at present two hundred and eighty bars daily, of eighty-five pounds each and worth seven hundred dollars per ton; the "San Felipe," the "Gen. Jackson," the "Temple," the "Tillie Castres," and many others.

About half a mile south of these lodes, nearly at the highest point of the Buena Vista mountains, are immense cappings of quartz that are conspicuously visible at a distance of from twelve to eighteen miles. In many places they are from twenty to thirty feet wide and rise up like walls to the height of from twenty-five to forty feet, and are traceable for miles in a southerly direction.

This lode, known as the "Boushey Lode" and the "Gem of the Desert," was located a short time ago by Stephen Boushey, and a tunnel commenced in a thorough and workman-like manner, designed to intersect it at a depth of two hundred and fifty feet. It is believed by many that this lode may prove the most valuable and extensive in the district. Most of the lodes heretofore mentioned converge toward it and inspire the reasonable confidence that it may prove the mother lode of the district, of which the others are mere spurs or offshoots. The number and magnitude of these mines leave no doubt that they will be successfully and extensively worked as long as any on the

continent, and that Cerro Gordo will ere long yield to no place in size and importance as a mining town. Hitherto, as we have indicated, a great drawback to the development of this mining camp has been the

Difficulty of Transportation

To and from it. This difficulty still exists, although with a fair prospect of speedy removal. Even under the comparatively limited extent to which these mines are now worked they are able to furnish constant employment to one hundred and twelve mule freight teams. These are more than can be obtained, and the removal of the bullion will always be a serious difficulty until the railroad is advanced to this place. Transportation has been recently somewhat facilitated by placing a small steamer on the lake. The furnaces are at the northern end, and the steamer conveys the bullion to the southern end, a distance of about thirty miles, where it is loaded on the wagons, for conveyance either to tide-water, via Los Angeles, or to the railroad, via this place. At present there are 18,000 bars of bullion, worth probably \$600,000, lying at the foot of the lake awaiting transportation. With the extension of the railroad to this place (which is promised in a few months), or if no more than the twenty mile section the Company is compelled to build by the 15th of July, under the terms of their charter, is completed this year, the difficulty in moving the bullion will be at an end, production will largely increase, and we may expect the whole of this valuable trade to take this route. No effort the people of Los Angeles may then make will suffice to attract any portion of it in that direction.

On the eastern slope of

The Buena Vista Mountain,

About two miles from Cerro Gordo, are also found a number of mines as rich as any in the district. The principal of these are the "Belmont," the "Wittekiad," and the "Friendship." These are mostly owned by practical miners who do their own work and sell their ore to Belshaw and Beaudry. Some of the ore from these mines is said to assay \$700 per ton. There are two furnaces in operation in Cerro Gordo, one belonging to Belshaw and the other to Beaudry. These turn out about fourteen tons of bullion per day, worth about \$28,000.

The Want of Water,

As we have before said, is a great inconvenience in Cerro Gordo. The limited quantity of this liquid that is used there at present, is obtained from a brackish spring three and a half miles distant. Six thousand gallons are used daily, and one hundred pick animals are employed to bring it. The wholesale price is seven cents per gallon and it retails at fifteen cents. Belshaw and Beaudry run three steam engines and they use for these and other purposes two thousand gallons of water per day, the remaining four thousand gallons are consumed by the hotels, saloons, stables, etc. None but expeditious and persons in affluent circumstances can afford to use it for bathing purposes. The sum expended for water is probably not less than six hundred dollars per diem. The spring is owned by one Chas. Duval and he finds it a valuable property.

Belshaw and Beaudry have a small spring four miles from the town, in a northerly direction, which they attempted to utilize for their purposes. It furnishes a very limited quantity of water. They laid pipes ¾ inch in diameter from it to their furnaces. As the surface was almost entirely a solid rock they could not inter them, and when the cold weather commenced this winter they burst, and they have since obtained their supply of water as above stated.

There is another spring eight and a half miles in a northerly direction from the town, but it is three thousand feet below its level.

It is evident that if an abundant supply of water could be introduced into the town, it would not only be of incalculable utility, but a source of immense profit to any company that could carry the undertaking into successful execution. If water could be supplied at such rates that every one could afford a fair supply, no doubt the aggregate amount paid for it would be just as large as at present, justifying the investment of an immense capital in the necessary works. Besides, if water could be furnished at moderate rates it would pay well to wash the ore free from all extraneous and earthy matter before the furnaces are charged with it. As this cannot now be done, there is a great absorption of metal in the slag, and low grade ores are cast aside.

This undertaking has been long discussed, and as the capital required was large, parties could not readily be found willing to engage in it. But we learn that a company has at last been formed for the purpose, composed of men of means and energy. The principal stockholders are Stephen Boushey and F. P. E. Temple who evidently mean business, as they have already let contracts for the construction of the works, which are to be completed by the 15th of July next, when they expect to have a stream of the capacity of ninety thousand gallons per day flowing into the town. They have incorporated with a capital stock of \$200,000, and besides the construction and maintenance of water works, they propose to carry on the business of gold and silver mining, to erect mills and smelting works, to purchase and sell mining and other properties, etc.

The point from which they will convey water is a noted spring, called "Diamond Spring," eleven miles south of Cerro Gordo, situated in a ravine fourteen hundred feet deep, in the midst

of the Inyo range. This spring is a large one, being the source of a considerable stream that flows eastward for many miles, until finally lost in the Saline Valley. It gushes from the granite rock, affording remarkably pure and sweet water, to the estimated amount of 120,000 gallons daily for the whole year. The water will be raised to the top of the ridge by means of pumps worked by two steam engines, through three inch pipes and thence conveyed through a four and a half inch pipe, interred a sufficient depth to be out of reach of frost, to the town, with an average fall of eighty feet to the mile, where it will be received in huge tanks for distribution.

It will be seen that this undertaking will require not only a large outlay, but careful and skillful engineering, and it shows that capital, proverbially timorous, has confidence in the permanency and continued productiveness of these mines.

The Trade of Cerro Gordo

Will build up a splendid agriculture and other permanent industries in this valley, results that do not die out with mutations in markets and other exterior circumstances. This kind of prosperity once established, is enduring and self-sustaining as long as seedtime and harvest continue, unless destroyed through political or moral causes. The great agricultural development of Los Angeles county was largely promoted by the trade of the mines, but it will not be injured by its withdrawal. It is a kind of development that is never barren of permanent good and is always sustained by the demands of universal human necessity.—*Kern County Courier*.

Borax in Kern County.

As already noted in the *Express* a very extensive borate deposit has been found in Kern county, at a distance of about 120 miles from this city. Specimens of the borate have been on exhibition in this office, and are seen to be of a pure and valuable quality.

The deposits discovered by Mr. H. J. Lent lie about 120 miles from this city, about three miles off the Owens River road near Harry Ball's station at Desert Springs. They were found about four weeks ago. They extended from Ball's house to the end of the marsh, about nine miles long and three wide. The borate is found in spots of, three or four acres, more or less. Messrs. Lent, Ball & Chapman's claims contain probably 500,000 tons of borate of lime; of course, they are the best deposits that could be found at the time. Mr. Lent, however, has no doubt that other deposits, equally valuable, though not so great in extent, will be taken up.

Mr. Lent has been in charge of the borax works at Columbus, Nevada, which, with those at Fish Lake, in the same locality, are the only borax deposits hitherto known on this coast, excepting those of Lake county. He thinks that these new discoveries contain a much larger percentage of boracic acid than the deposits at Columbus. He believes that there is room for the employment of a thousand men in these fields and those at Slate Range, sixty miles distant. He has refined some of the borate, and has made an excellent quality of borax, a specimen of which we have. He is having made at Harper & Dalton's some vats and other rude contrivances for the reduction of borate, which he intends to put up upon the ground, and, after reducing the borate there, to ship it to this city for re-shipment. He also thinks of putting up works there for refining, though he believes that it would perhaps be cheaper and better to have a refinery here.

We understand that a refinery, capable of reducing two tons of the borate per day, could be put up here for \$2,000 or \$3,000. He has full faith that the discovery will prove to be a very important one; and his experience in the business lends weight to his opinion.

The value of Nevada borax in San Francisco is \$560 per ton. There is a duty of about \$250 on English borax.

The manufacture of borax in England is said to be confined to one firm in Liverpool, which produces about 2,000 tons per annum, worth there about \$240 a ton.

We learn that the borate deposits have also been found at Slate Range, about sixty miles distant from the original discovery. A considerable number of locators are moving into the borax fields from Inyo and Kern counties, and several parties have gone from Los Angeles county. Messrs. Ansin and Baker, of this city, are by this time upon the ground, and will undoubtedly secure valuable locations.

This city should be the entrepot for the trans-shipment of this valuable article. There seems to be an almost inexhaustible bed of the borate, which will pay largely for shipping, and hundreds of men will no doubt soon be at work upon the ground. The borate is said to be of seventy-five per cent. purity; and the recent suggestion of a correspondent that a refinery for the manufacture of borax should be at once established in this city, is worthy of serious attention. This is a very important matter, and we ought to be active in taking advantage of this fortuitous discovery almost at our door. Let us not, by delay, permit others to reap the chief advantage from this valuable discovery.—*Los Angeles Express*.

GENERAL P. E. CONNOR, on the 28th ult., received a telegram from H. S. Jacobs, to the end that fifty miles of railroad iron and two locomotives will be shipped by the first of May for the Salt Lake, Sevier Valley and Pioche Railroad.

The Most Popular Medicine Extant.

1840. OVER THIRTY YEARS 1873.

Since the introduction of

PERRY DAVIS'

PAIN-KILLER.

THE PAIN-KILLER

Is equally applicable and efficacious to young and old.

THE PAIN-KILLER

Is both an internal and external remedy.

THE PAIN-KILLER

Will cure Fever and Ague when other remedies have failed.

THE PAIN-KILLER

Should be used at the first manifestations of Cough or Cold.

THE PAIN-KILLER

Is the Great Family Medicine of the Age.

THE PAIN-KILLER

Will Cure Painter's Colic.

THE PAIN-KILLER

Is good for Scalds and Burns.

THE PAIN-KILLER

Has the verdict of the people in its favor.

THE PAIN-KILLER

Gives universal Satisfaction.

THE PAIN-KILLER

Beware of Imitations and Counterfeits.

THE PAIN-KILLER

Is almost a certain cure for CHOLERA, and has, without doubt, been more successful in curing this terrible disease than any other known remedy, or the most eminent and skillful Physician. In India, Africa and China, where this dreadful disease is ever more or less prevalent, the PAIN-KILLER is considered by the natives, as well as European residents in those climates, a SURE REMEDY.

THE PAIN-KILLER

Each bottle is wrapped with full directions for use.

THE PAIN-KILLER

Is sold by all Druggists and Dealers in Family Medicines.

BAIRD'S BOOKS

FOR PRACTICAL MEN.

My new revised and enlarged Catalogue of PRACTICAL AND SCIENTIFIC BOOKS, 96 pages, 8vo., will be sent, free of postage, to any one who will favor me with his address.

CYANIDE OF POTASSIUM,

Which I can sell upon better terms than any other
dealer on the Pacific Coast.

I make three grades or qualities to suit the require-
ments of different consumers.
I will be glad to furnish prices to any person ad-
dressing me on the subject.

HENRY G. HANKS,
Manufacturing Chemist,
PACIFIC CHEMICAL WORKS, SAN FRANCISCO
24725-1f

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they
have no equal. No effort has been, or will be spared
to have them constructed in the most perfect manner
and of the great number now in operation, not one has
ever required repairs. The constant and increasing de-
mand for them is sufficient evidence of their merits.
They are constructed so as to apply steam directly
into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pen being filled, the motion of the muller forces
the pulp to the center, where it is drawn down through
the aperture and between the grinding surfaces.
Thence it is thrown to the periphery into the quicksilver.
The curved plates again draw it to the center, where it
passes down, and to the circumference as before. Thus
it is constantly passing a regular flow between the grind-
ing surfaces and into the quicksilver, until the ore is
reduced to an impalpable powder, and the metal amal-
gamated.

Setters made on the same principle excel all others.
They bring the pulp so constantly and perfectly in con-
tact with quicksilver, that the particles are rapidly and
completely absorbed.

Mill-men are invited to examine these pans and settlers
for themselves, at this office, 229 Fremont Street,
San Francisco

LEA & PERRINS'
CELEBRATED
Worcestershire Sauce.

Declared by Connois-
seurs to be the only good
SAUCE
Caution Against Fraud.

The success of this most
delicious and unrivalled
Condiment having caused certain dealers to
apply the name of "Worcestershire Sauce"
to their own inferior compounds, the public
is hereby informed that the only way to
secure the genuine is to ask von LEA &
PERRINS' SAUCE, and see that their names
are upon the wrapper, labels, stopper and
bottle.

Some of the foreign markets having been
supplied with a spurious Worcestershire
sauce, upon the wrapper and labels of which the names
of Lea and Perrine have been forged, L. and P. give
notice that they have furnished their correspondents
with power of attorney to take instant proceedings
against manufacturers and vendors of such, or any
other imitations by which their right may be infringed.
Ask for LEA & PERRINS' Sauce, and see name on
wrapper, label, bottle and stopper.

Wholesale and for export by the Proprietors, Worces-
ter: Crosse & Blackwell, London, &c., &c., and by
Grocers and Oilmen universally. 15724-1f

EUCALYPTUS.

The attention of the Medical profession is respectfully
called to the following preparation of this use-
ful agent. Eucalyptus and its preparations have been
found useful in obstinate cases of intermittent and Marsh
Fever, often supplanting the use of Quinine. The
paroxysms of Asthma and Catarrh are greatly controlled,
and in various Kidney diseases and Catarrh of the Blad-
der it seems to act like a specific.

FLUID EXTRACT EUCALYPTUS.

This extract represents in a concentrated form the
medicinal effects of the leaves of Eucalyptus Globulus
THE ELIXIR OF EUCALYPTUS.

This compound presents the properties of the leaves
in a palatable form and elegant appearance. Dose—
One tablespoonful, to be repeated as often as the case
demands.

Charactes of Eucalyptus Globulus, useful in
Asthma, Difficulty of Breathing, Incipient Pleurisy, etc.

Mining and Other Companies.

On the 12th day of April, 1873, the following companies have been organized, and the names of the shareholders are given below. The names of the shareholders are given below.

Angels Quartz Mining Company—Principal place of business, 408 California street, San Francisco.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of March, 1873, an assessment of ten cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the Corporation, Room 5 and 6, No. 302 Montgomery street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1873, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 21st day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

And in accordance with law and an order made by the Board of Directors, on the 4th day of March, 1873, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of Maurice Dore & Co., 327 Montgomery street, San Francisco, Cal., on Monday, April 21st, 1873, at 2 o'clock p. m., of such day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

GEORGE CONDON, Secretary.
Office, Room No. 1, 408 California street, San Francisco, California (np stairs). ap-3t

The Central Land Company—Principal place of business, 338 Montgomery street, Room 5, San Francisco, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of March, 1873, an assessment of fifty cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the Corporation, Room 5 and 6, No. 302 Montgomery street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1873, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 21st day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

F. B. HASWELL, Secretary of the Central Land Company.
Office, 338 Montgomery street, Room 5, San Francisco, Cal. ap-14t

Columbia Smelting and Mining Co.

Stockholders' Meeting: A meeting of the stockholders of the Columbia Smelting and Mining Co., for the election of a Board of Directors for the ensuing year, and for the transaction of such other business as may come before it, will be held at the office of the Company, Room 14, No. 408 California street, on the 30th day of April, 1873, at 1 o'clock p. m.

J. W. TRIPP, Secretary.

Eagle Quicksilver Mining Company—Location of works, Santa Barbara County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of March, 1873, an assessment of fifty dollars (\$50) per share was levied upon the capital stock of said Company, payable immediately in gold coin of the United States, to the Secretary, at the office of the Corporation, Room 5 and 6, No. 302 Montgomery street, San Francisco, California. Any stock upon which said assessment shall remain unpaid on Wednesday, March 19th, 1873, shall be deemed delinquent, and will be advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 24th day of March, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

WM. H. WATSON, Secretary.
Office, Room 5 and 6, No. 302 Montgomery street, San Francisco, Cal.

POSTPONEMENT.—The day for meeting shares delinquent on the above assessment is hereby postponed until Thursday, the 21st day of April, 1873, and the sale thereof until Monday, the 28th day of April, 1873, at the same hour and place. By order of the Board of Directors.

WM. H. WATSON, Secretary.

Frear Stone Company of California—Location of principal place of business and works, City and County of San Francisco, State of California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of March, 1873, an assessment of two dollars per share was levied upon the capital stock of the Corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the Corporation, Room 5 and 6, No. 302 Montgomery street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1873, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 24th day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

R. WEGENER, Secretary.
Office, 414 California street, San Francisco, Cal.

Gold Run Mining Company—Principal place of business, San Francisco, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of March, 1873, an assessment of ten cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the Corporation, Corner Market and Spear Streets, San Francisco, California. Any stock upon which said assessment shall remain unpaid on the 15th day of May, 1873, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 24th day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

O. C. PALMER, Secretary.
Office, Cor. Market and Spear Streets, San Francisco, California.

Hardy Coal Mining Company—Principal place of business, San Francisco, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of March, 1873, an assessment of one dollar per share was levied upon the capital stock of the Corporation, payable immediately in United States gold and silver coin, to the Secretary, Room 5, No. 302 Montgomery street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1873, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 24th day of May, 1873, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JOHN HARDY, Secretary pro tem.
Office, Room 5, No. 302 Montgomery street, San Francisco, Cal. m29-4t

Machinery.

IMPORTANT TO Quartz Mining Companies.

IMPROVED PATENTED Hardened Cast Steel Shoes & Dies.

The undersigned are prepared, at short notice, to furnish IMPROVED PATENTED HARDENED CAST STEEL SHOES AND DIES, for Quartz Mills of every pattern. This improvement supplies a want long needed by persons engaged in Mining enterprises.

They are more economical and cheaper than cast iron shoes, as they wear from four to six times as long, and crush a greater quantity, as they retain their full diameter, never chipping from the edges. This, with the time saved in replacing worn and broken iron shoes and Dies, and the great saving of freight to remote mills and mines, makes a vast difference in the cost of reduction of ores.

WE ALSO FURNISH
Cast Steel Tappets, Cams, Picks and Hammers,

Which possess the same advantages of Economy and Durability, and deserve the special attention of Miners and others engaged in quartz crushing.

The Superior Strength of these steel castings—the fact that they can be FORGED AND WELDED as easily as bar steel—their cheapness and great accuracy, as compared with forged iron—cannot fail to make them desirable for many purposes, where forged iron and steel have heretofore been used. Among such articles we mention:

ROLLING MILL CASTINGS,
Bevel and Spur Wheels, Guides, Spindles, Dies, etc.

AGRICULTURAL CASTINGS,
Reaper Guards, Plow Shares, Mold Boards, Plow Jointers, etc.

Anvils, Sledges, Vices, Masons' Hammers, Blacksmith Hammers, Mallets, R. R. Frogs, etc.

And other articles requiring solidity and great strength.

DONKEY ENGINES FOR HOISTING,
Mining Machinery, Etc.

Persons giving orders will send diagrams and measurements of Shoes and Dies, etc., as above.

J. G. KITTREDGE & CO.,
No. 515 California street, San Francisco.

Repairing done on very Reasonable Terms and in the best manner. No. 32 Fremont street, S. F. 19723-3m

Scaling and Foaming Prevented and Fuel Saved.

Enquirers are respectfully informed that

WARSOP'S AERO STEAM SYSTEM

Has been well tested, during three years, in England. Besides the above advantages, it greatly prolongs the life of Boilers, Tubes and Fire-bricks.

It is a cheap contrivance, and easily applied to any engine. Illustrated Circulars, showing the appliance and describing its advantages, are sent to all applicants.

All who are troubled with Scale and Foaming may rely on this system of prevention—also on saving at least 20 per cent. of fuel.

RIGHTS for States and for individuals will be sold on liberal terms.

J. L. SANFORD,

General Agent for United States,

420 Montgomery street, San Francisco,
And Box 909, P. O.

Information Required to Give an Estimate of Warsop's Apparatus:

- 1.—Diameter of Cylinder.
- 2.—Length of Stroke.
- 3.—Number and Length of Boilers—Tubes or Flues.
- 4.—Distance of Boilers from Engine.
- 5.—Can Pump Piston be attached to Cross-head of Engine?

It can, however, be driven by any of the usual appliances that work the Water-Feed Pump. These items will enable me to give a near estimate of the cost.

J. L. SANFORD, General Agent.

Notice is hereby given, that the copartnership heretofore existing between A. J. Severance,

Charles W. Randall and J. Gus. Burt, under the firm name of "Severance, Holt & Co.," is this day dissolved by mutual consent. A. J. Severance, having purchased all the interest of his late partners, will continue the business of manufacturing and setting Diamond Drills as before, under the style of A. J. Severance & Co. Dated San Francisco, Nov. 24, 1871.

Office, 315 California street. A. J. SEVERANCE,
CHAS. W. RANDALL,
J. GUS. BURT.

22723-4f

BURLEIGH ROCK DRILLS

—AND—

Air Compressors.

The Burleigh Rock Drills, which have stood the test of five years' constant use at the Hoosac Tunnel, and which are now in use in nearly every State in the Union, as well as in Europe and South America, are unequalled in efficiency and economy by any other Drilling Machine. They are of various sizes, and equally well adapted to Tunneling, Shafting, Open Cut or Quarrying, and will drill six to ten inches per minute in granite. They are driven by steam above ground. The Burleigh Air Compressor is the best engine yet devised for furnishing the "air motor" for the many purposes to which it is now being used.

They are to be used on the St. Gothard Tunnel, Switzerland; Tunnel 13 miles long. We refer to the following gentlemen and works:

Gen. Newton, U. S. A. Hell Gate Tunnel, L. I.
Mess. Shanley Hoosac Tunnel, Mass.
J. Dutton Steele Nesquehoning Tunnel, Pa.
Sidney Dillon Fourth Avenue Work, N. Y.
Col. Roebbing East River Bridge Company, N. Y.

For further information, etc., address

No. 314 CALIFORNIA STREET.

SAN FRANCISCO.

Manufacturers and have constantly on hand

SPORTING, MINING, AND BLASTING POWDER,

OF SUPERIOR QUALITY, FRESH FROM THE MILLS. It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market.

We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

We also call attention to our

HERCULES POWDER.

Which combines all the force of other strong explosive now in use, and the lifting force of the BEST BLASTING POWDER, thus making it vastly superior to any other compounded now in use.

A circular containing a full description of this Powder can be obtained on application to our Office.

BROWN'S PATENT LAMP.

One of these Lamps, when placed at a distance of 200 feet from the bank, will light up a bank surface 250 feet in length and 150 feet high, and to a much better advantage than any other light heretofore tried, and at an expense not to exceed five cents per hour. Lamps furnished at short notice.

Letter of Recommendation.

Mr. C. B. Brown—Sir: Your Patent Lamp for lighting hydraulic mines, which you sold to me in December last, has given entire satisfaction, and far exceeds my expectations, and I think it the best and cheapest light ever used to light mining claims by night, and am satisfied that I have saved three hundred dollars by the use of it in the last mining season over pitch or any other light of the same brilliancy; and I will also say that if I could not get another lamp, five hundred dollars would not buy it. Yours,
W. D. APLIN,

Little York, Nov. 5, 1872.

For further particulars, address,
1622-tt C. B. BROWN, Placerville, Cal.

DEWEY & CO.,

American and Foreign

Patent Agents.No. 338 Montgomery St.,
SAN FRANCISCO.

Established in 1860. Inventors can rely upon the surety and dispatch of all important and confidential business entrusted in our hands. Long familiarity with Mining, Farming, and all other classes of inventions on this coast, enables us to give the most intelligent advice to Pacific Coast Inventors of any Agency in the Union, and oftentimes save unnecessary delay and expense. Every branch of the patent soliciting business attended to. All worthy inventions patented by us will be liberally noticed, free, at the most desirable time for the patentee, in both the MINING AND SCIENTIFIC PRESS and the PACIFIC RURAL PRESS.

Interferences Prosecuted.

Opinions Rendered regarding the Validity of Patents and Assignments.
Rejected Cases taken up and Patents Obtained.
Every Legitimate Branch of Patent Agency Business promptly and thoroughly conducted.
SEND FOR CIRCULAR.

HINTS FOR We will send on receipt of stamp for postage, FREE, our 32-page Circular, containing 112 Illustrated Mechanical Movements; a digest of PATENT LAWS; information how to obtain patents, and about the rights and privileges of inventors and patentees; list of Government fees, practical hints etc., etc. Address DEWEY & CO., Publishers and Patent Agents, San Francisco.

Valuable Premiums for Subscriptions.

A Sewing Machine
of Real Value
(Beckwith's)
given for \$40
worth of Sub-
scriptions.

The AMERICAN AGRICULTURIST, in speaking of this Machine, says:
We are prepared to endorse the Beckwith Sewing Machine as one worthy of being at once secured by all who cannot purchase the expensive machines.

1st. It is well and strongly made.
2d. It is easily attached to any table or stand having a leaf or edge projecting an inch or so, and can thus be used in any part of the house, near a window, etc.
3d. It makes a stitch as loop stitch (the same as the Willcox & Gibbs and some other good machines), which with a little care in making the closing stitch is abundantly strong for nearly all kinds of sewing, and less liable to break in washing and wearing, owing to its elasticity.

WE WILL GIVE

For \$12, a Machine and the Illustrated Press, 1 year.
For \$12, a Machine and the Mining & Scientific Press, 6 mos.
For \$12, a Machine and the Pacific Rural Press, 6 mos.
For \$13.50, a Machine and the Mining & Scientific Press, 1 yr.
For \$13.50, a Machine and the Pacific Rural Press, 1 year.
For \$40, we will give a Machine and \$40 worth of subscriptions to either paper or all jointly. Send for Circular.

Express charges must be paid by the purchaser. Address, for further particulars, the PUBLISHERS OF THIS JOURNAL.

Ashcroft's Patent Steam Gauges,

(Original—with Bourdon Spring).

Steam Gauges,
Vacuum Gauges,
Registering Gauges,
Test Gauges.

Low Water Alarms, Gauge Cocks, Glass Water Gauges, Cylinder Cups, Self-Oilers, Foiler Felting, Solder's, Tuck's, Hemp and Soapstone Packing, Stocks, Taps and Dies, Twist Drills, Drill, Lathe and Planer Chucks, Emery Wheels, Etc.

Every description of Engineers' and Machinists' supplies, for sale by
TREADWELL & CO., San Francisco.
2v26dt

THE TANITE COMPANY.

Manufacturers of SOLID EMERY WHEELS From 1 inch to 3 feet in diameter. EMERY GRINDERS for Stone Manufacturers, Foundries, Machine and Rail Road Shops, Planing Mills and Saw-Mills. Emery Wheels and Saw Gumming Machines for sharpening and gumming GANG, MULAX and CIRQU-LAR Saws. A judicious use of Tanite Emery Wheels and Grinding or Gumming Machines, will more than repay the cost in this year's work.
Write for circulars and Photographs to THE TANITE CO., Stroudsburg, Monroe Co., Pa. 9v26-6ml6p

THE PRALL CONDENSING STEAM PUMP.

The Cheapest, Most Reliable, Most Durable and Most Economical Pump in Use.

This remarkable Pump, though having been used extensively in the Western States for the past year, is now for the first time offered to the trade of the Pacific Coast.

It is adapted to the raising of water or other liquids, under all possible conditions where steam can be obtained, operating absolutely without machinery with more economy and less liability to derangement than any Pump in use. As a MINING PUMP its advantages are most obvious.

The steam is condensed instead of being exhausted into the shaft or tunnel. It is not affected by mud, sand or grit, having no working parts to wear or cut out.

It is economical of steam, because all friction is avoided, and the steam is made to do double duty, that of direct pressure and then by condensation, utilizing the atmospheric pressure to lift the water to the Pump.

It requires no lubrication nor any attention whatever.

For IRRIGATION and raising water for stock purposes, the Prall Pump is vastly superior to anything ever before invented.

It requires less steam to elevate water from 20 to 30 feet than would be necessary to move any other style of Pump doing no work.

It is so simple that any one of ordinary intelligence, however unaccustomed to machinery, can operate it.

They are constructed of seven different sizes, with capacities ranging from two to fifty thousand gallons per hour.

Boilers furnished with the Pumps when desired.

Manufacturing Agents, Pacific Iron Works,

P. O. BOX 726, SAN FRANCISCO.

JOS. WAGNER,

113 and 115 Mission Street.....SAN FRANCISCO.

MANUFACTURER OF
**FRENCH BURR
MILL-STONES**

—AND—
Portable Mills.

—ALSO—
MILLS

Especially adapted for
GRINDING QUARTZ.

AGENT FOR DUFOUR & CO.'S CELEBRATED

Dutch Anchor Bolting Cloths.
BOLTING CLOTHS MADE UP.

Eureka Smut Machine, Bran Dusters, Mill Irons, Spindles, Bails, Drivers, Steps, Regulating Screws, Silent Feeders, Pulleys, Proof Staffs, Hoisting Screws, Bails and Pins, Conveyor Flights, Plaster and Leather Belting.

Mill Picks, Mill Picks Dressed, Mill Stones Re-
paired and Rebuilt.

Mill Stones Balanced with FELLEBAUM'S PATENT BALANCE, of which I am sole proprietor for California, Oregon, and Washington Territory. 15v26dt

**THE GIANT POWDER COMPANY**

Are now manufacturing besides the famous regular

GIANT POWDER, A NO. 2 GIANT POWDER,

Somewhat slower in its Explosion, which we recommend for

BANK BLASTING, COAL MINES,

AND FOR ALL SUCH WORK WHERE THE ROCK IS NOT VERY HARD

It is fully as safe as the other and evolves neither smoke nor noxious fumes when exploded.

Price. 50 Cents per Pound.

The sales of both grades increase very fast, which is the best proof of their superiority over other explosives.

They have proved to be the most durable and economi-
cal Saws in the World.

Each Saw is Warranted in every respect.
Particular attention paid to construction of

Portable & Stationary Saw Mills.

MILLS FURNISHED AT SHORT NOTICE
At the lowest Market Prices.

HALLIDIE'S

Patent Endless Wire Ropeway.

Covered by Numerous U. S. Patents.

IMPORTANT TO

Mining Companies, Civil Engineers, Con-
tractors, Etc.

The system of transporting material, such as Ores,
from the mine to the mill, Earths for embankments,
Rock from quarries, etc., by means of steel wire rope,
has been well tested and found more economical,
advantageous and reliable than any other method
of transportation; and to the annexed certificate in con-
nection therewith I beg to call the attention of those in-
terested:

EUREKA, Nevada, July 10, 1872.
T. M. MARTIN My dear sir: On your leaving for San
Francisco, it gives me great pleasure to hand you my
written acceptance of the HALLIDIE TRAMWAY put
up by you upon our mine in Freiburg.

It is a perfect success, discharging ten tons of ore per
hour with two men's labor. It is perfectly simple in
construction, and, as far as I can judge, there is nothing
about it to ever get out of order—nothing to wear out.
While our requires but about two thousand five hun-
dred feet of wire rope, I can see no reason why the line
could not be extended almost indefinitely with equally
happy results. Again, the carrying capacity might be
doubled or quadrupled if desired. After several weeks
trial upon our mine, the unanimous verdict of all who
have seen it is a complete, unquestioned success. If
this can be of any service to you, use it in any way you
think proper. Very respectfully, O. O. GOODWIN.

EMMA HILL CONSOLIDATED MINING CO.,
Little Cottonwood, Utah.

Superintendent's Office, Sept. 23, 1872.
T. M. MARTIN, Esq., Sir: The Ropeway constructed by
you (HALLIDIE'S PATENT) for the Emma Hill Consoli-
dated Mining Company, has been built in a most substantial
and workmanlike manner, and is at this time in splendid
working condition. I most cheerfully accept the work for
the Company, and recommend it to others wishing a sure
and speedy transit for ores over places impracticable for
wagon roads, etc. Respectfully,
L. W. COLBATH, Superintendent.

"The Vallejo works smoothly with the elevated wire
tramway, which carries its load of ore as quietly and easily
as if there was no winter or snow in the world."

"Whatever the objections to wire tramways may be on
account of their cost, I have seen nothing yet that even
approaches them in the facilities they afford for moving
ore at all seasons of the year."—Correspondent Utah Min-
ing Journal, Alta, Jan. 8, 1873.

The Vallejo Ropeway.

The Vallejo Tunnel Company's Tramway Little Cot-
tonwood, built on the HALLIDIE PATENTED PLAN, is a
complete success. It is between 2,500 and 2,600 feet in
length, and is supported by thirteen stations. The fall in
the distance is about 80 feet, and the wire rope, which is
three-fourths of an inch in diameter, will easily and easily
deliver one hundred tons in six hours. The machinery is
automatic, loading and unloading the sacks or binnets.
About one ton and a half can be sent down at once.
The stations are about two hundred feet apart, and the entire
apparatus is strong and safe. As the wire rope is elevated
about forty feet above the surface of the hill, the Tramway
can be worked all winter long, without the slightest trou-
ble.—Utah Mining Journal, Salt Lake, Sept. 23, 1872.
Mining Companies and others desiring to negotiate for
the erection of this system of Ropeway, can communicate
with me personally, or through Postoffice Box 964.

A. S. HALLIDIE, Patentee,
112 and 114 California Street, SAN FRANCISCO.

WIRE ROPE

For hoisting from mines, transmitting power, ship rigging,
etc., of all kinds and sizes, on land and made to order.
Wire of all kinds and descriptions, furnished at lowest
rates. A. S. HALLIDIE, 112 and 114 California St.

California Pioneers.

In speaking of the early days of California, we are too apt to place our dates to correspond with that of the immigration incident to the discovery of gold, and thus the '49-ers, as they were called, bore off, to a great extent, the palm and credit really due to more adventurous spirits than themselves.

We should go back nearly a decade, or to '41, and crown with the laurel of adventure the really early pioneer—for it was in that year that the first company, headed by Robert H. Thomas, not as hunters and trappers, but as a company of adventurers, determined to see what they could see, and appropriate, if they saw fit and right, first traversed "the plains," crossing by the same route, via Salt Lake, Humboldt river, and the Sierras, that afterwards became the great highway of the overland immigration of 1849 and onward, and that only ceased when the iron rail had spanned the continent.

It is to the few who remain of that band of brave spirits composing that first overland company that we dedicate the engraving presented herewith: for now

All broken in that little band,
Patient of toil and strong of hand,
Who left Atlantic homes to rear
An Empire's proud foundation here.

We present in our illustration the company just as they are winding over the first rugged height that brings to their view the distant Sierras. With what exultations of joy and triumph they beheld the rounded peaks, lifting their snowy turbans to the skies, can only be appreciated by those who in later years made the same tedious journey, though to a great extent left of the sufferings and dangers incident to the first adventure, when

"The Indian from his lodge of bark,
The grey bear from his den,
Beyond their camp-fires' wall of dark
Gazed on the mountain men."

We could give the names of the men who composed this adventurous band, but as many of them now "sleeps the sleep that knows no waking," it would seem like calling them from the tomb; and though our first interest is ever with the living, we are glad to do honor to the memory of the men of this pioneer band of 1841, who, when resting for the first time under the shadows of the mountains, that after 170 days of weary toil they had at length reached,—

"All night above their rocky bed,
They saw the stars march slow,
The wild Sierras over head;
The desert's dearth below.

Still upward turned with anxious strain,
Their leader's sleepless eye,
Where splinters of the mountain chain,
Stood back against the sky.

They set their faces to the blast,
They trod the eternal snow,
And, faint, weary, bleeding, halted at last
The promised land below.

Behind, they saw the snow-cloud tossed
By many an icy horn;
Before, warm valleys, wood embosomed,
And green with vines and corn."

THE EPIZOOTY is expected to be in this city in a few days, as they have it in Oakland, San Jose, and elsewhere in our vicinity. The disease is, however, in a mild form.

Death of an Inventor.

English papers announce the death of Mr. R. W. Thompson, best known in this country as the inventor of the rubber tire for road engines. Mr. Thompson, though quite a young man, (41) had become quite noted as an inventor. His first invention was made at the age of nineteen, and consisted of a device for firing blasts by electricity. This invention was brought out under the patronage and by advice of Faraday. He commenced his experiments on india-rubber tires in 1844, when he was but 22 years of age; but made very little progress at that time from the fact of the scarcity and costliness of rubber. He invented a steam crane and hydraulic dock in 1860. He was the

Mining Suits.

An injunction suit has been commenced in the Circuit Court by B. B. Titcomb, of Boston, Mass., against Michael Dougherty and Willis Jones. The complaint alleges that on the 2d of June, 1869, the defendants were the owners of the Miners' Ditch and the Union Ditch, in Placer county, and the water rights appertaining to them. The Miners' Ditch has its origin in Short Tail Cañon, and the Union Ditch in Black Hawk Cañon. The Miners' Ditch runs across Black Hawk Cañon in a flume, and the waters of the Cañon flow along the natural bed into a dam, and then into Union Ditch, save from the 5th of November, 1872, to the 7th of March, 1873, during which period the defend-

Utilizing Water Power on this Coast.

We notice that the surveying party who have been making a survey of Russian River to ascertain whether there was water and fall enough, have finished their work. The route surveyed was impracticable and they will shortly look for another. They ascertained that there was 73 feet fall from Soda Rock to a point in the river just east of Healdsburg. It is to be hoped that a practicable route for conducting the water will be found so it will greatly assist manufacturing enterprises. The Healdsburg people are in earnest, and wish to establish factories at their town which will have the great advantage of water power. Some attention is being turned to the Truckee River, for

the same purpose. That river never freezes and it falls about 40 feet per mile. There is said to be no danger of overflow, and every four hundred yards from Bigler to Truckee, facilities for natural water power exist, and the same is the case from Truckee down to Reno, about 35 miles.

With the great scarcity or inferior quality of coal in the State, we should utilize all the water power attainable. The great difficulty has been that these facilities for water power, are at such a distance in the interior or away from railroads, that the advantage of the cheap power, is overcome by the cost of freight on the materials and products; therefore, manufacturers found it more to their advantage to use steam here at San Francisco, than water power in the interior, notwithstanding this comparatively high cost of fuel. Moreover, many streams which afford water power in the winter and spring, are

too low towards the middle, and end of our summers, to be available for that purpose. With an increase in railroad construction, we had hopes that this state of things would cease, and that the banks of many different streams would be the location of various manufacturing enterprises, all run by water power. This is not yet the case for reasons before mentioned. In some localities it is found almost as cheap to transport freight by teams as it is to use the facilities afforded by the railroads, since the railroad charges are so high. Time and competition may reduce these tariffs, in which case there is no doubt but that many mills and factories of different kinds will be established where water can be used for the power required.

BORAX.—Prospectors from the lately-discovered borax deposits near Desert Springs station on the road to Owens river, report locations made for miles. The borax is found in spots and varying in thickness. The deposits on the Seate Range, 200 miles northeasterly, in San Bernardino county, are even more extensive. Vats for reducing the borax, and other appliances, have been ordered, and crusts of borax are taken out and piled, resembling hay-ricks, for reduction or shipment.

THIRTY-TWO hundred acres of mining land have been surveyed and located on Buckeye Mountain in Del Norte county.

FIRST VIEW OF THE SIERRAS BY CALIFORNIA PIONEERS.

first to conceive the idea of a band saw, and also the elliptic rotary engine, both of which, however, were afterwards worked out by other heads. He was destined by his father for the pulpit; but an invincible hatred for Latin barred his path in that direction, led him into more practical studies, and finally introduced him to the mechanical and scientific world, where he found himself quite at home. It is said that when a boy of some 16 years he manifested a great fondness for experimental chemistry and electricity; so earnest was he in the prosecution of the former, in his lodging room, which he had fitted up for a laboratory, that his parents found it prudent to assign him a separate building where frequent explosions might become less harmful to others.

Mr. Thompson was a great sufferer for many years, and his death was not unexpected by his friends.

RAYMOND AND ELY VS. HERMES.—This very important suit is still going on in Pioche, and is exciting a great deal of attention. The mass of testimony is so voluminous that it is impossible for us to give it in full, and a condensed report would be very unsatisfactory. A decision will probably be given very shortly, and the local papers will then most probably give a digest of the case, which may be interesting to our readers.

MINERS at Bannock, Idaho, are busily engaged preparing for mining operations, and look for moderately good times.

suits diverted the waters into flumes of the Union Ditch where it crosses Black Hawk Cañon. On the 2d of June, 1869, Dougherty and Jones being the owners and in possession of Union Ditch and the water privileges in and to the waters of Black Hawk Cañon, sold the same to O. W. Henderson, who, on the 1st of November, 1872 sold said ditch to plaintiff. This ditch is constructed from Black Hawk Cañon to the town of Yankee Jim's, in Placer county, for the sole purpose of carrying water to be used in working the Davis mine. The defendants are the owners of a mine, and needing a large supply of water did, on the 5th of November, 1872, divert the water from Black Hawk Cañon for their use until the 7th of March, 1873, when it was stopped. The defendants now threaten that they will again turn the waters of the ditch, and plaintiff asks for an injunction enjoining them from doing so. A temporary injunction was granted by Judge Sawyer and an order that the defendants show cause why it should not be made perpetual.

A suit has been instituted in the Nineteenth District Court, by William C. Coley, against the well known firm of Cross & Co. The complaint alleges that Cross & Co. agreed, with one John A. Robertson, that in the event of the consummation of the sale of the Keystone mine, situated in San Luis Obispo, they would pay him \$2,000 for his services in effecting the sale and the transfer of all his interest in the extension east of the mine. The sale of the mine was consummated after some considerable trouble, and Robertson transferred his claim to Coley who now demands judgment for the sum named.

CORRESPONDENCE.

A Rambler's Ride Over Rough Roads.

There are more things in this world, Horatio, Than are dreamt of in our mean philosophy.—*Hamlet*.
 EDITOR PRESS.—Who am I? I guess stranger you'd give a "red" to know. Well, I'm not all at once going to acquaint you with my affairs, pecuniary, private, personal, or political; suffice it to say that I was horn and have lived all my life a "rambler." I have had a hard time "of it since Mother Nature first took it into her hand to make me an inhabitant of this little" skittle ball; many a shaking and rough tumble have I had over its puny circumference. Many a shakehands with rough and ready pioneers of civilization and progress, and now find myself as the French say, "dans cettesleir," without knowing where to go, what to do, nor how to do it. In fact, I have come to California, like Paul Pry of fame, just popped in; I hope I don't intrude and I wish to give you a few of my ideas of what is doing in your beautiful country, if you will let me have my own way, and tell what I know in my own fashion, for I'm a "hard nut to crack" if you don't let me have my head to myself. Suffice it then to say, that I dropped down into Montgomery Street, a few days since, from "t'other side of Jordan," and feel pretty much as useful as a bull in a China store.

My first impressions of your city were that I was not wanted at all. Stocks were nowhere. Brokers looking "broke." "Wild Cats" without tails, a "Bear" Garden without a Picador "to bull up." "Judas Iscariot," I exclaimed, of what earthly use shall I be here. "No one to love me, none to caress." What must I first turn to. I looked in your newspapers, saw no advertisements of "Help Wanted" except the following: Wanted—A bootblack, good wages, apply, etc. Wanted—A man to do chores round a stable. Wanted—A bedmaker for a hotel, up country, etc., *ad infinitum*, *et nauseandum*. What can this mean, say I, have I come to this Paradise, after spending \$500 and two months hard life on board ship, merely to get employment as a shoeblack, etc.? for which positions in social life I find myself quite incapable, (please Mr. Editor, consider this as a private communication,) or am I to wait until some intelligent stranger dives down into the recesses of my waistcoat pockets, and finding that I am pretty considerably "froze out," will put me up to a way of getting an honorable subsistence, without taking a pleasure trip to San Quentin, or making a tour round the admirably arranged police establishments or caravansaries, open for the welcome of the "Robert Macnives" of your city. No, say I, I'll first stick to my old "game" of rambling, and as, during the last 25 years, it has allowed me to remain out of the "Alms-house" although I've frequently rubbed a little of the "whitening" off its exterior on the back of my \$25 dress coat, I'll try it again; so off for the road.

(Shooting over valleys, riding over ridges, Grooving under tunnels, skimming over bridges; Obi! 'tis a pleasant thing—this riding on the rail.)
 And here I am, up in the air "higher than a kite," in Virginia City, Nevada. Oh, what a change this is from your beautiful Frisco. No streets, no stores, no lumps, no beautiful nymphs like those which grace Kearny street from four to seven p. m., on an ordinary week day. Through shanties; tumbled down rockeries; low gambling hells; wretched stables where the devil's spirits are "retailed" for a "quart" a glass, (such benzue or morphine shop) called *par plaisance* saloons; a hotel; a theater, closed, upon which the moss of ages seems to have proved the "thin" quality of its former troupe, and in which Shakespeare must have been long since "torn to tatters;" and the remaining habitations so thickly grouped and scantily built that one would suppose they were peopled at the time of the "flood," and used only as a means of escape from the prevailing deluge. Here, thinks I, must be the "Ultima Thule" described by Eneas, or the "Inferno," so prettily sketched by my friend Dante. But where are the Cyclops? It is 8 a. m. and not a living being—except a dog, who has seen better days, and looks as if the "wool had been long since pulled over his eyes"—is to be met with. Hurrah! I detect a German coffee shop; I enter, mein herr von Deutschland gives me a fraternal salute. In half a minute a smoking "bifteck" and a good cup of coffee were before me—geniune. What an appetite this cold mountain air (7,000 feet) gives me. I eat, I talk, and like the witch who "maunched, and mauched, and mauched," I feel, conscientiously, that my Teutonic friend will make a loss out of the four bite which I pay him for my repast, and ask him to hob-nob a glass of lager at the next saloon.

Here, one by one, enter weird beings, dark, grinning and unctuous, who drink dark lager or pure spirit, and silently look upon me with the disgust with which my stranger-looks evidently inspire them. I cannot tell the reason I am so hateful, but guess it is because they perceive that I am no miner—only a tourist, a worthless individual who has merely come to have a look at them.

I feel like a fish out of water, so say good

bye to my host, and take a walk along the mountain. Such wild scenery I have never before seen. Not a plant, not a tree, not a cabbage. The whole view before me, looks like a vast range of volcanoes; below, the Savage threatens me with a savage mein; the Belcher helices out fumes of noxious gasses. All is still, save the boom of the machinery. Below, there, in fumes of hot, suffocating atmosphere, stripped nearly to the skin, sweating and working, are the inhabitants of this extraordinary region. Who can tell what those subterranean caverns have given rise to in our world's history. What wars, crimes, bloodshed and misery have been worked through their instrumentality? and yet thousands of lives are annually used up in their service.

I cannot help thinking that money is the root of all evil, and that from the pit's mouth it works its fatal charm upon the victims of its malevolence. No quiet homestead, no peaceful valley is to be seen: all is apparently desolation and darkness! I return to the mountain top, and now the town becomes full of life. Hundreds of strangely-dressed people "are congregated in the street." Indians with their squaws, alike wretched, are to be met with in groups, a few buggies, with their owners in rough coats, a few stragglers in the stores and all is seen of Virginia City. I feel glad when the preparatory whistle of the engine shows that it is time for me to get aboard of the train, and my mind through the night wanders in a dreamy mist of ideas through the strange scenes which I have witnessed, but can so imperfectly and faintly describe. In my next I hope to be able to give some observations in regard to the famous mines of this region. But now, Mr. Editor, I must take my leave of you for the present; so good by till next time, and please to remember I owe Wo Sing a washing bill and am "dead broke."

Yours truly, RAMBLER.

The New York Money Market.—Threatened Trouble Ahead.

[Letter from an Occasional Correspondent of the Press.]

DEAR PRESS:—You will find everywhere a set of regular croakers who make it their especial business to go about in the most doleful fashion prophesying wholesale ruin, immediate and unavoidable on all sides. New York is no exception to this rule. New York has its croakers, as has every other important commercial centre. Now, I too am going to put in my croak. Don't condemn me too hastily. Don't associate me with the venerable brotherhood of croakers, as a life member. I am only *in pro tem.*, so to speak.

If I am to have out my croak, it is incumbent on me to show that there are good grounds for it. Perhaps if I prove that I am one of an immense army of croakers, my Cassandra—like assertions may carry more weight.

First, then, who are the chief croakers at present? Not the birds of ill omen who, whenever the market happens to be a little tight, (as between seasons, in the Fall and Spring), augur the speedy realization of their dismal forebodings. Not mere speculators who are on the look-out for a general depreciation of prices on the one hand, or a corner in money on the other; and who hope, by promulgating wild talk, to affect the market as they wish. These two classes of men may be relied upon about as confidently as the Millerites, in the way of this cheerful sort of prophecy. No; it is not from them we should seek trustworthy information. Ask sound business men who are disinterested—or, at least, have nothing to make. These all agree. Notice for yourself the general drift of conversation on the street. Mark the despondent look worn by the business parts of the city. There is but one answer, a single solution: *we are on the verge of great financial trouble.* Already proofs of this grave truth are evident.

If there were no solid ground for fear, the prevailing opinion of things would be enough to cause great difficulty. It takes very little to start a land-slide, when everything is ready. In financial matters it is the apprehension, rather than the reality, that usually does the work. Whenever a considerable number of parties, anticipating a crash, begin to call in loans, mortgages and credits, that crash is precipitated.

But we have not only vague, undefined rumors, but many actual failures. There is great monetary distress at the South—more, perhaps, than at any time since the war. A member of a prominent dry goods house in this city tells me that, out of five hundred accounts kept with Southern jobbers, they have had over twenty bad failures—averaging about thirty cents on the dollar—since the first of January. In every other line of business the same complaint is made. To be sure, the dry goods interest is always the first to suffer, but it is still a pretty accurate barometre for the rest. The weaker banks are going down, right and left. Within a couple of months three in New Orleans; two here; many scattering. And now the Bull's Head Bank, which was in high popular confidence, has to suspend. Naturally enough, the officers do not like to acknowledge this to be the result of simply bad management and throw out mysterious hints about embezzlements. All hosh. From all accounts this

is a good square collapse, if ever there was one.

I have mentioned the prevailing distress at the South as one cause of difficulty here. Another tightening influence, and a most powerful one, is the certainty of a speedy resumption of specie payments. And yet it is not exactly the certainty of resumption—for that all count on—but the uncertainty as to the precise epoch of resumption. If this were definitely settled at (say) three, or even two years, time enough would be allowed for large operators to draw in their horns gradually. The market would, in such case, find its level by degrees, without any very violent commotion when it was voted to resume. But as to the facts of the case, we are liable at any time, from the tone of the last Congress, to specie resumption at short notice. Here we are, in a most woefully patched up state, financially.

Look at the state of the currency. With all the talk about its inflation there have been occasional stringencies; and these have been met by our "Fiducial Providence," (as somebody calls Mr. Bontwell), by tossing overboard a few more millions of paper each time trouble was experienced. Thus we have been going from bad to worse, each temporary relief in reality but aggravating the disease. Actual contraction of some fifteen per cent, is bad enough; I do not know but that I am justified in saying that the dread of it is worse.

After all, perhaps the main cause of the present uncomfortable condition of things is to be found in the unusual mania for stock-speculation. There have been such violent fluctuations in leading stocks that a large number of outsiders have come upon the street. This withdraws from production and legitimate business an enormous amount of capital and indirectly injures the country to an incalculable extent. It is comforting to reflect that of those who venture among the Wall street animals, most come out badly bitten. Everything is compensated for, in this world.

There seems to be but one way of staying off great national distress, and that is Mr. Bontwell's plan of still further inflation. This idea is entirely too homeopathic to suit our old school business men. What we do want is adequate legislation—or, better yet, none at all—and plenty of European capital. Without these all temporary makeshifts are useless and worse than useless. ALBERT WILLIAMS JR.
 New York, March 29, 1873.

An English View of Our Iron Trade.

We copy the following interesting article from the *Colliery Guardian* a journal of the coal and iron trades, published in London:

The iron trade of the United States is clearly acquiring more and more importance day by day. In 1871, the production of pig iron in sundry counties of the great metallurgical State of Pennsylvania was as follows:—Alleghany, 47,618 tons; Armstrong, 26,573 tons; Bedford, 17,055 tons; Berks, 36,971 tons; Blair, 7,078 tons; Cambria, 25,047 tons; Carbon, 25,927 tons; Chester, 18,077 tons; Clarion, 6,041; Columbia, 16,002 tons; Cumberland, 3,567 tons; Dauphin, 25,822 tons; Erie, 8,292 tons; Fulton, 4,912 tons; Fayette, 85 tons; Huntingdon, 1,800 tons; Lancaster, 65,285 tons; Lawrence, 39,805 tons; Lebanon, 59,286 tons; Lehigh, 159,059 tons; Luzerne, 23,211 tons; Mercer, 59,872 tons; Mifflin, 8,557 tons; Montgomery, 71,975 tons; Mouton, 31,333 tons; Northampton, 106,718 tons; Perry, 3,553 tons; Schuylkill, 25,607 tons; Union, 4,231 tons; and York, 4,161 tons; making an aggregate of 923,527 tons. The total production of pig in the United States in 1871 was estimated at 1,900,000 tons. The growing importance of American metallurgy may be illustrated in another form and in other words. In 1854, the annual consumption of rails in the United States was 147,658 tons, of which 339,439 tons were imported, and only 108,016 tons were manufactured in the Great Republic itself. It follows that in 1854, of the total consumption of rails in the United States less than one-third was of American manufacture, while more than two-thirds were imported. In 1872, the consumption of rails in the United States amounted to 1,504,591 tons, of which 975,000 tons were of American manufacture, and 529,591 tons were imported. The old order of things was thus reversed, about two-thirds of the rails used by the Americans last year being made in the United States, while one-third was of American manufacture. American statistics place the imports of foreign rails into the United States in 1872 at 523,591 tons, and British statistics show that British railway iron was exported last year to the Americans to the extent of 472,760 tons, leaving a balance of 50,831 tons derived from other sources. These other sources were Belgium and France.

The general conclusions which may be drawn from the data which we have been summarizing are—first, that American metallurgy has acquired during the last twenty years—and this in spite of the serious national troubles with which the Republic has been afflicted—a very great development; and secondly, that vast as this development has been, it has been outstripped by the still more rapid progress of the American consumption of rails and other descriptions of iron. The vigor which has been displayed in the prosecution of new railroads in the United States during the last four years has been marvellous, and the existing systems have also been improved and extended as they have increased in productivity and importance, so that on all sides there has been a growing and extraordinary consumption of railway iron throughout Brother Jonathan's

vast dominions. Those dominions are, indeed, so vast that one cannot at present discover a limit to the extent to which the work of American railroad construction may be carried, and the price of rails is practically the only consideration which has to be taken into account. If the Americans had only Great Britain to rely upon as regards their rail supplies, the construction of American railroads would probably have now to be, in a great measure, suspended; but American energy has been equal to the occasion, and we have now statistical evidence of the fact that two-thirds of the rails required for American railroads have been made of late in the United States themselves.

The present aspect of the iron question in the United States possesses much interest for the iron trade of Great Britain. So long as the Americans could obtain supplies of rails from this country at a reasonable price, they were content to import them with a certain freedom; but in exact proportion as British rails have risen in price, they have applied themselves with increased energy to the development of their own metallurgical industry. Never at any previous period of their history have the Americans devoted so much energy to the working of American coal and the production of American iron as in 1871 and 1872; and just as coal and iron have become dearer and dearer in Great Britain, so have the working of American coal and the production of American iron been still further stimulated. The result of this new order of things in the United States is reflected in a marked diminution in the American consumption of British railway iron. In the first two months of 1872 we sent the Americans 88,430 tons of our railway iron; in the corresponding period of this year the corresponding exports sank to 48,901 tons,—showing the alarming declension of 39,529 tons. As American orders for British iron are executed to a large extent in Wales, the fact to which we have just called attention possesses an especial interest for that strike-distracted portion of the empire. It may be an unwelcome truth, but it is a truth notwithstanding, that unless the wretched labor disputes, fomented by interested parties, which for so many months past have afflicted the iron trade of this country, can be healed—and healed, too, in good, sober earnest—the bewildering prosperity which appeared to be dawning upon British metallurgy will pass away like a dream; and in districts marvellously endowed by nature, and once resounding with the hum of happy industry, labor will be compelled to fold its idle hands and lament the folly which reduced it to profligate inaction.

Westinghouse Brake on Driving Wheels.

Commenting on an accident in which the locomotive broke loose from the cars after the brakes were put on, the *Pittsburgh Commercial* says:

"The great importance of applying the brakes to drivers, as well as to the cars, has been forcibly demonstrated in the Mifflin accident. In a train of several cars, each car has its proportion of the weight of the locomotive to overcome. This weight is (independent of the tender, which has its own brake,) about thirty-five tons, making a weight of about six tons to be overcome by each car, besides its own weight. This strain is not equally exerted between each car, but is, of course, the full amount between the locomotive and tender, and six tons less to the coupling of the next car, and so on.

"If there was a sudden jerk, it could not have been given by the break, or by reversing the engine. In either of these cases the train would be closed instead of stretched apart.

"There are instances on record of cases where the reverse lever of the locomotive has slipped forward, of its own motion, after having been reversed, and would make a tremendous jerk, sufficient to break any coupling. The fact of the immense strain being applied to the couplings would at first seem to have caused them to break, but it is well known that the strength of the couplings is sufficient to stand several times the amount of strain that would result from the application of the brakes.

"If the engine has been reversed, the strain would have been almost nothing upon the various couplings, as the locomotive would have taken care of fully one-half of its own weight. If the air brakes were applied to the driving wheels of the locomotive, as well as to the other wheels in a train, there would be no strain upon any of the couplings, while the efficiency of the brake would be increased to a great extent.

"The Pennsylvania Railroad has applied the air brake to the drivers of several of their shifting engines, and it is found to be at least twice as efficient in stopping trains as engines are when reversed.

"It seems common sense would suggest that efficient brakes should be put on the locomotive, and thus prevent all strain on car couplings, as well as provide against the locomotive breaking loose and running into the train ahead.

"In the Mifflin case, after the couplings were broken, the engine would lose part of the help of the cars, and so would apparently shoot forward and run into the train ahead; but in reality the train, after being relieved of the weight of the engine, would stop sooner than it otherwise would have done."

MECHANICAL PROGRESS.

Air Power.

A letter from Brunswick, Me., to the *Portland Argus*, gives the following information relating to the use of air as a motive power in that village:

"On the Androscoggin river, some three-fourths of a mile below the railroad station, is the site of a mill, long since burned, and the motive power which operates the condenser is a water wheel at the place. The wheel, it is said, is capable of driving four condensers of equal power with the one now in use. But it is only with results already accomplished, that we have to do. At the railroad station is an engine of ten-horse power, running circular saws for sawing wood and various machinery in the blacksmith shop in the vicinity. Thence a small pipe passes on through the village, furnishing power to Worthing Brothers, jewelers, who are running a small engine of about one-horse power. Parent and Dufriend also use an engine of two-horse power in their blacksmith shop; Dennison & Co., box makers, an engine of two-horse power, and Professor Brackett, of Bowdoin College, one of three-horse power, for the manufacture of instruments, while the laboratory of the college has one of six-horse power. That, nominally, this small condenser furnishes in all twenty-four-horse power, and all unite in saying that the air power is much more efficient than steam in working the same engines; it does not drag, but recovers itself instantly from any strain or check, and is in every way a success."

REMARKS.—The employment of pneumatic power for industrial purposes is constantly increasing. By its use the Mt. Ceniz tunnel, through the Alps, seven miles in length, was bored. The Hoosic tunnel, in Massachusetts, five miles in length, now nearly finished, is being cut by the same means. The St. Gothard tunnel, in Switzerland, lately commenced, which is to be thirteen miles in length, will also be cut by means of compressed air. The Hell Gate rocks, under the East River near New York city, are in process of removal by the same agency. In planing mills, the pneumatic method is used to carry the shaving from the planers to the furnaces of the steam boilers; in grain and wool houses, to convey the stock. At the iron furnaces pneumatic elevators are used to lift the cars and their loads of ore from one point to another. In London the pneumatic method drives five ton freight cars in tubes under ground; the post office department of that city has now in use several miles of pneumatic tubes laid under the streets in which letters are conveyed with great rapidity.

In this country the largest scale on which the system has been applied is at the works of the Pneumatic Transit Company on Broadway, where a railway passenger car, running in a nine foot tunnel under that street, is operated by compressed air. For an underground railway this pneumatic method is especially useful; fumes, gas, smoke, dust, noise and locomotives, all are avoided; the cars may be driven smoothly along with great rapidity. In England, some years ago, during the experimental trials of the pneumatic cars, the trains were driven by this method at a velocity of sixty miles per hour.—*Am. Artizan.*

Novaculite.

Novaculite is usually made use of for the purpose of sharpening tools and domestic implements, and is commonly called whetstone. Geologically, it belongs to the millstone grits. Its first condition undoubtedly was sandstone, and by the aid of a chemical process, performed by nature, became pure silica. A great deposit, from which thousands of tons have been mined for hundreds of years, is situated near Constantinople. There are also two or three other deposits known in Europe, but none of so good a quality as the one at Constantinople. The most remarkable deposit of this kind was found in Arkansas about the year 1840, some two miles from the celebrated Hot Springs. The quarry was first worked in 1843; but only for the past few years to any great extent. The demand is quite extensive, and stones sold at from 50 cents to \$1.25 per pound, ready for use. The vein of rock is very peculiar, presenting twelve to sixteen feet of width, and carrying with it on either side the same rock, but of a much more coarse and inferior quality. The dip of the formation is 40 to 45 degrees, and seems to become more uniform the deeper the vein is mined. The deposit of red oxide of iron, in some portions of the vein, gives to it the appearance of a fine marble. Its discovery was made by its cropping out upon a quite extensive hill owned by a gentleman by the name of Barnea, who holds in this an independent fortune. The finest portion mined brings a large price, and is largely used by engravers. In the Cedar and Taney counties in this State (Missouri) the same rock is found, but no development has determined its extent, save surface specimens, which are not likely to represent the best rocks of the formation; as in the Arkansas mine, the deeper it is mined, the more superior the stone becomes.—*St. Louis Journal of Commerce.*

High Pressure Steam and Compound Engines.

Compound cylinders are supposed to be so adjusted, that the work done in each cylinder equals half the whole work; that is, the expansion in the first cylinder equals the expansion in the second. The difference in cylinder room, it must be noticed, is very much in favor of high pressures, as it diminishes in each case as the pressure increases. Thus the area of piston required at 300 lbs. is only half that required at 20 lbs. pressure in a condensing engine. And it is to be noticed that in the compound engines the necessary increase is much smaller for high pressures than for low pressures. At 20 lbs. the high pressure cylinder has half the area of the low pressure cylinder. Whilst at 300 lbs. it has only about one-twelfth.

Now as regards the strength of the engine. This is the great objection to the use of high rates of expansion. The machinery of an engine to work at 300 lbs. must, only to do the same work, be seven times as strong as that which works at 20 lbs. Here, then, is a fatal objection against the use of steam at high pressures, unless it can be met in some way. This is where the advantage of compound engines comes in: while the pressure in the one increases from 76 to 438, the other increases from 63 to 112. Thus by the use of compound engines the pressure on the piston can be kept quite within reason.

Again—by the use of steam at 100 lbs. we may do with little more than half the coal required for a pressure of 14 lbs. with only three-quarters the cylinder room, and shall only increase the greatest pressure on the piston by about 10 per cent. With 300 lbs. we do with 20 per cent. less coal than at 100 lbs. with two-thirds the cylinder room, and we must increase the strength of the machinery by 40 per cent.

We must look for economy by increasing the ratio of expansion and the use of high pressure steam so far, and only so far, as is necessary for the expansion for engines in which the release takes place at or below the pressure of the atmosphere. There will be advantage in pressures at least up to 120 or 130 lbs. Beyond this it must be a question for experience to decide how high we shall go.

In such engines as use a blast we shall find that there is great economy in using very high pressures of steam, provided the rate of expansion is increased. Thus, in a locomotive in which the blast was fixed at 30 lbs. it would be much more economical to use steam at 200 lbs. and expand four times, than at 100 lbs. and expand twice, and the blast would be much the same.—*Prof. Osborn Reynolds.*

AMERICAN MACHINERY IN EUROPE.—It is a pleasant and noteworthy fact, says the *Boston Commercial Bulletin*, that the demand for machinery of American make of all kinds is growing rapidly in favor in countries which have hitherto looked to England as the only proper source for such appliances. At the present time we send locomotives to Russia and Austria, shoe and leather-working machinery to Switzerland and Mediterranean countries, pulp-reducing machinery to Spain and Portugal, and tailors' shears to England. Besides these there is an ever-increasing demand for agricultural machinery, in which our superiority is acknowledged, and our sowing machines are so far ahead of all others that those of foreign make are seldom or never thought of. Our weed-working machinery, too, is attracting the attention of the Old World, although they have less use for it than we.

INTERESTING AND VALUABLE DISCOVERY.—It is a recent French discovery, that adding a minute quantity of gelatine to a solution of sulphate of copper, prevents the brittleness which copper is said to have that has been deposited by the action of the galvanic battery. The softness and malleability of copper deposited from a solution of a copper salt by electrolysis is increased by increasing the conductivity of the solution. Thus acid added to the bath until it has reached the point when the hydrogen gas is about to be driven off, will hasten the decomposition, and the copper obtained will be soft and pliable. But what gelatine does to produce an effect, or rather why, we do not understand.

IRON VESSELS for the transport of spirits are found to be free from many of the defects of wooden ones, especially such as cause loss. They are made of sheets less than one-tenth of an inch thick, of cylindrical form, about 47 inches long and 32 inches in diameter, with ends slightly convex. The bung is closed by rubber disks, and protected by wood hoops on each side; there are thin iron hoops around each end, and the interior is protected from rusting by a coating of gum or dextrine.

EARLY SAWS.—An English writer says that every one who knows anything about saws, their use, and history, knows that the first saws of which we have any trace or record were thin-backed, so that the cutting edge should work freely; setting out the teeth is of more recent invention. The old saws preserved in the museums show this construction.

CAR WHEELS AND AXLES.—It is stated that 104 patents have been granted in this country upon car axles and wheels having the idea in view, of making car wheels to run independently, as in turning a curve.

THE PRESERVATION OF EXPOSED SHEET-IRON. The direction of the government railroads of the Netherlands has published the results of some experiments in regard to the preservation of sheet-iron used in railroad bridges. From 32 sheets half was cleaned by immersion for 24 hours in dilute hydrochloric acid; they were then neutralized with milk of lime, washed with hot water, and while warm dried and rubbed with oil. The other half was only cleaned mechanically by scratching and brushing. Four of each kind were then equally painted with red lead, with two kinds of a red paint of oxide of iron, and with coal tar. The plates were then exposed to the weather, and examined after three years. The result was, 1. That the red lead had kept perfectly on both kinds of plates, so that it was impossible to say if the chemical cleaning was of any use. 2. That one kind of iron oxide red paint gave better results on the chemically treated plate than on the other; in fact, a result equal to that of the plate painted with red lead, while the other kind of iron oxide red gave not very good results on the plates, when only scratched and brushed. 3. That the coal-tar was considerably worse than the paint, and had even entirely disappeared from those iron sheets which had not been treated chemically, but only cleaned by brushing.

SOLUBLE GLASS IN THE ARTS.—The employment of this substance in the arts is rapidly extending, and it has become indispensable in many industrial branches. It seems to be especially well adapted to the production of cements. When intimately mixed with fine chalk, it is found that a hard cement will be formed in from six to eight hours. With powdered sulphide of antimony a black mass is produced which is susceptible of taking a high polish, and possesses then a superb metallic luster. Fine iron dust gives a gray-black mass of great hardness. Zinc dust gives a gray mass of much hardness, and having a metallic luster. Zinc castings can be readily repaired by its aid.

MEASURING THE INTENSITY OF COLORS.—A new device has been prepared for measuring the intensity of colors, which consists of two pieces of glass, touching at one end, and held apart at the other by a strip of platinum. Upon one of the plates a series of fine lines is engraved; and the intensity of any two colors is determined by comparison of the depth of liquid which it is necessary to add before the lines referred to shall become invisible.

SCIENTIFIC PROGRESS.

Progress in Chemistry.

The university of Leipsic possesses one of the finest and best equipped laboratories in Germany, with no less a person than Professor Kolbe as lecturer on chemistry. Recently a thick octavo volume of nearly 700 pages has been published, giving a detailed account of the original investigations made in that laboratory for the past six years. The results of nearly, or quite, all of this work were published to the world from time to time as each investigation was completed; but the collection of them together in book form impresses us with the magnitude of the work, and shows how much can be accomplished in a single institution. Of course, many of these investigations are the direct product of Professor Kolbe's fertile brain, and equal results cannot be expected everywhere. But some results like these, though fewer in number and of less importance, ought to be produced in a dozen of our highly endowed American institutions, where to-day the dust lies deep on long unused apparatus.

It may be objected that these investigations have neither led to startling discovery, nor brought in much money to the investigator. But science can point out so many occasions where the pursuit of knowledge for her own sake has benefited the world at large, that this charge will not avail much among the thoughtful, and especially among intelligent capitalists and inventors. From the time when Priestley discovered oxygen or Liebig prepared chloroform, to the time when Hoffman discovered the beautiful aniline dyes that bear his name, the most valuable and beneficial chemical inventions have sprung from the study of science for her own sake.

Nature can be compared to the wary heiress, who repels each suitor who, as she thinks, is courting her for her money, and bestows her heart only on the true lover who, ignorant of her wealth, adores her for herself alone; and like the cautious heiress too, she often disguises herself as a pauper to test the devotion of her followers. On the other hand, the fortune seeker, who marries the milliner's apprentice in the expectation that she will turn out a millionaire in disguise, deserves the disappointment; and science often thus disappoints her mercenary followers.—*Scientific American.*

SYNTHESIS OF ACETIC ACID.—M. M. Thenard has communicated to the French Academy an experiment which is an important step in the direct synthesis of organic substances by the re-action of inorganic substances. The passage of the electric current from a Ruhmkorff coil through a mixture of the gases, carbonic acid (CO₂) and proto-carbide of hydrogen (CH₂), creates a colorless fluid, which is simply acetic acid C²O₂.

THE POLAR EXPLORING EXPEDITION.—It appears by all accounts from the extreme north, that the temperature of all seas which bathe the Arctic islands, equally with the temperature of the air, has been very much higher during the past summer than in former years, and this thermometric anomaly has extended to the Orkney Islands and Scotland.

These facts are highly suggestive of the ice-conditions in the circumpolar basin, with which the American, Austrian and other Arctic explorers were probably contending till the long winter of the high north set in, and would seem to fully explain the silence of all the explorers, which has continued unbroken for an unusual length of time. Upon this supposition that the ice-drifts were made unusually large by the great excess of heat, and drifted southward in July, leaving an open sea behind them, Capt. Hall's, and the various other expeditions would doubtless have improved the opportunity to push boldly forward to the highest attainable latitude.

As all the outstanding exploring parties were furnished with boats suited to just such a happy emergency, it is highly probable that one or more of them has progressed toward the Pole beyond the utmost limit ever before reached.

IMPACT OF BALLS.—The deduction from all the experiments is that when the ball is arrested instantly by any obstacle which it cannot at all penetrate, a small portion of the ball—the anterior portion—is raised to a high heat; but that when it penetrates any substance little or no heat is developed. A ball fired so as to strike the anvil in a darkened room, gave off at the instant of impact a quite lively yellowish light, showing that great heat was developed; but it is only a very small portion of the ball which is thus heated. Although the heat of that portion which first comes in contact with the obstacle, and is arrested instantly, may be so great as to produce fusion, and even volatilization, the remaining portions expend a considerable portion of their vis viva in crushing the metal between them and the obstacle; and this latter effect, being mechanical, does not develop heat.—*American Artisan.*

WOOL AND COAL ASHES.—It appears to be a matter of no little surprise, with some, that while the ashes from most woods are highly charged with alkali matters, no such matter is found in the ashes of mineral coal; although we are taught that such coal is derived directly from woody substance. The reason of this is found in the fact that the change from wood to coal is made in the presence of water, by which all the alkaline matter is abstracted by solution; mineral ingredients—chiefly silica—being substituted in place of the alkaline matter, thus adding to the bulk of the ashes, but rendering them useless as a fertilizer, except for the mechanical action which they exert upon clay soils, rendering such soils more loose and friable.

A NEW FUEL.—A manufacturing chemist, Mr. John Sellars, of Birkenhead, England, has invented a novel composition of matter for use in the place of coal, cannel, etc., in the manufacture of illuminating gas. The composition consists of a mixture of sea-weed, sea-grass, sea-rack, or the like, with coal tar, pitch, bitumen, mineral oils, etc., either with or without peat, charcoal, or other carbonaceous matter, which mixed matter is subjected to destructive distillation in retorts. The advantages claimed are more effective separation of the light hydrocarbons; second, increased yield of carburetted hydrogen, and the production of coke particularly valuable in the manufacture of metal-foundries' blacking.

SCIENTIFIC ASSOCIATION.—Next to books on meteorology and cognate sciences the best way of learning these matters is by classes, in which men may combine and interchange their thoughts and observations. The greatest savans find this, and have their geological, botanical, astronomical, royal societies, British and American associations for the advancement of science, and what not, in which all may know what each has done, and each share in the learning of all; for, as iron sharpeneth iron, so a man sharpens the face of his friend.

THE TEMPERATURE ABOVE THE CLOUDS.—M. Tissandier states that in a late balloon ascent from Paris, he reached a height of 6,560 feet above the earth, where, having passed through layers of clouds, he found a bright sunlit sky and a temperature of from 63° to 65° Fah. When descending and re-entering the clouds, which were in a highly electric state, the temperature decreased to 27°, and the balloon was surrounded by small crystals of ice.

VOLATILIZATION OF IRON.—Iron is not volatile, except at very high temperatures, like gold and platinum. Dr. Eisner, director of the Berlin Porcelain Works, has tried the experiment of subjecting a small piece of iron, in an unglazed crucible, to a long-continued exposure to a temperature of over 3,000 per cent., when he was distinctly enabled to recognize minute needles of crystallized iron on the cover of the crucible, the result of vaporization.

TO DETECT COTTON IN SILK FABRICS.—A French Chemist has discovered that a strong solution of chloride of zinc will dissolve all the silk threads from any mixed textile fabric, leaving intact any cotton fibres. The practical value of this preparation for removing stains from cotton goods will be apparent unless it affects the color.

to drill on the ore seam as soon as practicable. Have several streaks, from which fair assays have been made, which looks as if there was a ledge in the vicinity of Raymond & Ely.

Dispatch from the Superintendent dated the 12th inst.: "I shipped yesterday, \$33,000. The twenty-stamp mill with new boilers, will start on Monday."

Dispatch of the 14th says: "The twenty-stamp mill, with boilers, started this morning."

Rye Patch.
The amount of halion received on the 14th was 3 bars, weighing 1,451 ounces. The Superintendent writes that the yield is improving every day, and the yield of ore is daily increasing. Have shipped 10 car loads of ore to Winnemucca to be redressed.

Sierra Nevada.
After the 5th says the result of the last clean-up of tons of ore worked gave halion to the amount of 1,260. Nothing new in mine or mill; everything working smoothly.

After the 12th says the mine prospects about the same last month. The southwest streak holds its size, but not prospect quite so well. The old stopes just about their own. The main north drift from the upraise is starting to-day, that looks as though they would get pay. The other prospecting drifts are being pushed ahead as fast as possible. No ore in any of these drifts yet. The runs splendidly.

Silver Hill.
After the 13th says they started the Bacon mill to-day. Everything is in order and all runs smoothly. Since starting air pump the air in the mine is splendid. Think will make a cessation with the Justice in a few days. Received at the mill to-day 61 tons 1082 pounds of ore from the Silver Hill mines.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior in proximity to the mines mentioned:

California.

AMADOR COUNTY.

JOHNIX-Cor. Amador Ledger, April 12: This mine for the management of Mr. Reese is turning out a large amount of rich ore. On the 500 and 600 ft. levels there is a well defined ledge 48 ft. wide of good paying ore from this immense lode, but a small amount of ore is necessary to keep their mill running. Mr. Henderson is his work thoroughly, and any man might well be proud of the showing he can give in this mine. Their mill under the superintendency of Wm. Hooper is turning out the bullion at the rate of 5 to 10 pounds per day.

Alpine Mines and Mills is running on good pay. This mine will in all probability be a first-class mine when they get down 700 ft. and drift 300 ft. to the east.

Grove mine is down 400 ft., and they are running level east to strike the ledge which they expect to find within 50 ft. of the shaft.

CLAVARAS COUNTY.

OLVERINE-GOOD CLEAN UP-Calaveras Chronicle, April 12: This mine is developing splendidly, promising equal if not eclipses, any other mine in the country. Recent crushing of 141 tons yielded \$2,750—an average output of \$19.50 per ton. But the result of the crushing, valuable as it is, is not a fair test of the quality of the ore. The rock was all obtained in sinking the shaft, and as such is of course, contained a very considerable portion of extraneous matter. Previous crushings of same character of rock—care being taken to separate debris of the mine from the ore—paid \$25 per ton, and there is no question but that the entire ledge will yield fully as well. The shaft is now 300 ft. in depth. Lode showing 3 1/2 ft. wide in the bottom. The work of sinking the shaft is being pushed on as fast as possible, and as soon as practicable stopping will begin.

T. Volviline is fully supplied with the latest approved machinery, and everything connected with the mine is first-class. The mill is capable of crushing 15 tons per day, and as an abundance of rock to keep constantly in motion can now be obtained, the monthly yield of the mine will probably average from \$7,000 to \$8,000 in the future.

ELERANTINO-Calaveras Citizen, April 12: This mine, commonly known as the Scieffard mine, has purchased engine and boiler formerly used at Doak's saw-mill. Mr. Swinge has taken the contract to deliver the same, and the hoisting-works and pump will be started immediately.

Role Center This claim, situated in our town, turning out beyond expectation. A large deposit of cement has been reached, where the gold is visible thick quantities as to dazzle the eyes of the workers.

Wicks.—The Big Mine has sunk its shaft 600 ft., and is now drifting toward the vein at that depth. The mill is running full capacity on rich rock taken from the 500 ft. level, we expect that this valuable mine will march on to wealth, with accelerated speed. The Wicks mine has ground up all of the rock which had on hand, and is now sinking its shaft deeper. The mill is closed for the present, and all of the hands, except six, are discharged, as no more are needed for sinking. As soon as the shaft goes down to the depth of one hundred feet, the mill will start up again, and the usual number of men be employed. The "Sick" never looked better than now.

ERN COUNTY.

MINERA-Havilah Miner, April 12: This Co. is working 16 stamps night and day, and turning out more rock to the mill can crush.

Wicks.—The mine is now perfectly opened, and Mr. Walker & Co. are taking out a large amount of high grade rock, rich in gold sulphurets. The ledge is nearly 8 ft. wide.

DE WALKER.—This mine which has remained idle for undated eighteen months ago, has been bought by Hon. P. T. Colby, who has associated himself with some of the best mining experts of this Coast, E. Q. Burk. These gentlemen have purchased a pump of 100 ft. lifting power and will start at once to take the ore from the mine, after which a large force will commence to extract rock, which will set the 20 stamps running again.

BUZZLEY BEAN MOUNTAIN.—The owners of these newly discovered mines contemplate the erection of an 80-stamp mill at an early day on the industry; the largest of the three Bear ledges. It measures from 5 to 10 ft. from top to wall; runs nearly 3,000 ft. on the surface and give a prospect anywhere.

PAUL.—This new mine, discovered about 2 months ago, is feeding 4 arrastras constantly with what is supposed to be the richest rock taken from the Kern mines this year. (No clean up yet). Good estimates think it will average between \$75 and \$100 per ton.

One of these mines were in operation last year, and can truthfully say that there will be 50 tons of rock shipped in Kern this year where there was one last.

VADIA COUNTY.

MINING AT COLFAX.—Nevada Transcript, April 10: "The prospecting in the vicinity of Colfax are improving. The Rising Star mine, with a five-stamp mill, mining only in day time, after a run of one month, yielded up \$5,200. The mill is now running night and day, and they have a 22-inch ledge, which looks splen-

dilly. The Rising Star never looked better than at the present time."

Big STRIKE.—Nevada Transcript, April 15: We heard a report in town yesterday that a man named Cash was had struck a pocket in Red Hill, near this city, and took out \$2,000 in gold. This was certainly a good cash haul for him.

PLACER COUNTY.

DETROIT FLAT.—Placer Argus, April 12: The business of mining is being pushed vigorously at present, and all the working claims are in full blast. The Placer claims cleaned up for the last run \$2,892.20; the Hume-Ticket, \$2,400; the Pacific, \$7,000; the Emuc-price, \$3,055; the Deep-shaft—not for pay, but for experiment, \$1,170; and the Central, \$4,430. These claims are all owned by the Cedar Creek Co., and each run from 40 to 45 days of 12 hours each, according to miners' estimate, though in fact they ran from 20 to 23 days and nights. From the commencement to the end of a run the water is not shut off except for necessary repairs or unforeseen accident of some nature. Each claim is supplied from the company's ditches with from 500 to 1,000 tubs of water, besides which the company's sales of water for March amount up \$9,363.51, and it is reliably known that the company's net earnings for the month exceed \$16,000. The Summit Company have run and fully completed their tunnel, and are washing an 8-ft. bank, from which they will be able to clean up a most little sum reaching into the thousands.

SAN DIEGO.

PULJING.—San Diego World, April 5: The mine are producing a large quantity of mail about the entire belt or system of auriferous quartz veins, from the Owens to the Golden Chert, a distance of over 8 miles, will convince the most skeptical of our real worth.

The Owens started their new hoisting works to-day, and will probably have their mine clear of water by Friday night, when workmen will commence active operations in sinking and stopping their already opened levels.

The San Diego is being worked steadily. A lot of ore having been worked recently, they paid a profitable dividend to the owners.

The Helvetia has resumed work, an interest having been lately purchased by the irrepressible "Count," who has no doubt made as usual a lucky strike. The Helvetia has been improving steadily as depth is attained. Searching for croppings on the Big Blue Hill has been resumed by several parties, and as usual with good results.

The Good Hope mine has recently struck a fine vein of excellent ore.

The Great Eastern is being worked on a lease and is paying well.

The Hayden is turning out a large quantity of fine ore. In the Canon general activity prevails. The Chaparral, Atlelope, Madden, Pacific, Kentucky, Ready Relief, and other mines are turning out splendidly.

The Golden Chert have their new mill nearly completed, and will commence crushing ore from their mine on Monday next. There are now about 500 tons of ore on the dump, and they are taking out better ore than ever. The company are engaged in running a level to connect with the air shaft at a depth of 120 ft. When that level shall have been completed, they will be able to stoop back to that will furnish at least 5,000 tons of ore.

TUOLUMNE COUNTY.

RICH STRIKE.—Tuolumne "Independent," April 12: Two Italians named Paganini and Rolero have been so lucky as to strike a vein of gold-bearing quartz near Cherokee, which is extremely rich. Our informant says that he has seldom seen richer rock.

GEM.—This quartz lode, located about 1 1/2 miles N. W. of Columbia, was discovered a short time since. It is a good milling vein, about 6 ft. wide, and the rock is easily broken, and is a fine material for prospecting \$12 per ton. The shaft is down on the lode about 60 ft., and the rock improves as they go down. Expect to sink 100 ft. in depth, when they will, if the present prospect holds good, make arrangements to put up a mill and work the mine with energy and system.

PAYS WELL.—Hill & Marshall, brought to town, Monday last, 65 1/2 ounces of amalgam, valued at about \$1,000, crushed by an arrastra from about 30 tons of rock; \$35 per ton is not bad work to have in a vein.

OLIVER GAVEL CLAIM.—This claim, recently purchased by James Tulloch, is at the lower end of Peoria Flat, and running into Table Mountain, and contains about 25 acres, with a depth of gravel from 15 to 20 ft., and prospecting all the way from one to fifty cents to the pan. The claim will be worked with hydraulic, with a fall of about 200 ft.

CONYER.—The quartz vein was discovered and located last fall, and lies one-half mile east of the Laurel Mill, above Cherokee. They have run a tunnel 200 ft., and have just struck the vein, which will average 1 ft. in width. The character of the rock is crystallized, showing decomposed iron, galena sulphurets and gold.

Nevada.

WASHOE.
BELCHER.—Gold Hill News, April 12: Daily yield, 500 tons, from the 1,000, 1,100, 1,200, and 1,300-ft. levels—the last-mentioned level yielding now about 110 tons per day of very fine, rich ore, which is taken out through the Yellow Jacket shaft. The mine is on a level above, about 50 ft. from the Corn Point line is finished, with the exception of a few ft. of timbering at the lower end. The main incline is down 104 ft. below the 1,300-ft. level, and in her rock. The drift north from the 1,200-ft. level is in 218 ft., and the drift south, to connect with it, is in 347 ft.

CHILLAS-POTOMI.—There is but little change in either the looks or daily yield of the different ore producing sections of the mine, and the work is being pushed on as fast as possible. The ore-breasts in the north mine at the first station continue to yield the usual quantities of good ore, keeping the Sapphire mill steadily running. The main west drift at the second station (500 ft. level) is making good progress, the rock in the face blasting well.

CROWN POINT.—Daily yield 600 tons. The 1,300-ft. level is turning out a vast amount of the very best ore, and the 7th floor above the car-track shows unusually rich to gold. The cross-cut east from the 5th floor is in about 50 ft., in splendid ore all the way, and the indications are that the body will prove to be of great width at that point. The drift south at the 1,400-ft. level is progressing well, as is the main incline, which is now down 150 ft. from the top of the shaft.

GOV. VINCENNA.—The main north drift on the 1,157-ft. level from the Gould & Curry shaft is still driven ahead, with no interesting change to report for the week. Sinking the shaft to complete the connection with this drift is making excellent progress.

DANBY.—The work of sinking a new shaft about 1 1/2 miles north of the old works, near the ledge on the Danby ground, is making rapid progress, the shaft being already down 25 ft. The shaft will be sunk 250 ft. and a drift then run for the ledge at this point, which is known to contain pay ore.

GOULD & CURRY.—The main south drift on 1,600-ft. level, to connect with the north drift from the Savage, is making steady progress with no change of interest to note. The north drift from the main east drift on the 1,5 ft. level is still driven ahead, with no developments of material value during the week.

HALE & MONROE.—There has been but little change in the general appearance of the 800-ft. level during the week. The ore-breasts between the 1,400 and 1,600-ft. levels are still working up to the usual average, and the daily yield has decreased to about 40 tons. The main drift south on the 1,700-ft. level is still driven ahead, with no change of material interest to report. The cross-cuts on this level have failed so far to develop any valuable ore bodies.

JULIA.—The main west drift at the 1,000-ft. level has advanced about 2 1/2 ft. during the week, without material change to report. Two new levels, one east and the other west, are commenced in the drift 150 feet south from the main west tunnel. The west cross cut is in 20 ft., still in ledge matter. The east cross-cut is in 10 ft.

JUSTICE.—Some fine ore has been developed in the east drift on the 400-ft. level during the week. Prospecting in other portions of the mine continues as usual, with a small excellent prospects of good developments in a very short time.

KENTUCK.—The prospecting work on the 1,300 ft level has failed, as yet, to disclose any extensive ore bodies. Knickerbocker.—The main drift west is still pressed vigorously ahead, the face in ledge matter, with occasional streaks of ore, some of which give excellent assays and promise good results when the cross-cutting of the ledge shall take place.

OVERMAN.—The main west drift on the 1,000 ft. level is still pushed steadily ahead without change of interest for the week. Both the north and south side drifts are making fine progress. Each of the 3 drifts have made about 25 ft. advance during the week. Preparations are being made to again resume sinking the shaft in a very short time.

SAVAGE.—The main drift north on the 1,600 ft. level, to connect with the south drift from the Gould & Curry, is still making fair progress, with no material change to report. The main drift south on the 1,600 foot level is driven steadily ahead, with no disclosure of value for the week. The ore body in the west cross-cut in this drift has not proved either as rich or extensive as was hoped when it was struck. The other cross-cuts have failed to develop any considerable bodies of ore on this level, as yet. The main south drift on the 1,700 ft. level is still pressed vigorously ahead, with but little change.

SILVER NEVADA.—Daily yield 60 tons of ore, keeping the mill steadily running.

WOONVILLE.—Oms mill, the Rumsdell & Thompson, starting crushing ore from this mine this evening or tomorrow morning, and the Lons mill day after tomorrow. The mine is in fine working condition, being well worked, with \$150,000 of ore on hand.

KENTUCKY.—The prospecting work on the 1,300 ft level of the pump wheel of the pump, bearing a day or two since, the pump is unable to keep the water in the 1,500 ft. level properly reduced, therefore work at that point is stopped for the present. In 2 or 3 days, however, all will be right again and drifting east resumed. At the 1,400 ft. level the company are drifting both north and south in the vein matter from the main east drift, and showing in from the mine 400 ft. north, or 300 ft. from the Confidence line, which has been sunk from the 1,300 ft. level, 130 ft. from the Confidence line is still progressing, but here, as well as at other prospecting points mentioned, nothing more than very good indications.

Montana.

NATIONAL MINING AND EXPLOSION CO.—Rocky Mountain Gazette, April 2: This Co. started up their mill, in Unionville, this morning, with some certainty of long and profitable work since early in January it has been vigorously developing the mine, and also putting mill machinery in better order. The mine now presents a most satisfactory appearance, and within the last week or two its force has steadily augmented to thirty-five men underground, besides the necessary surface hands. Quartz is now being so rapidly stooped out that considerable quantities have to be stowed away in the mine to await the time when the hoisting apparatus can overtake the work, and the quartz-dump is growing large at a rapid rate.

RAPID DIGGINGS NEAR SHERIDAN.—Montanian, April 3: News came in last evening that once again the diggers have been successful in their search for gold. The discoverers are sure that they have opened out what will prove to be a "big thing." The new discovery is said to be bar and hill diggings, and easily worked. A \$20-nugget was picked up on Monday.

Utah.

EMMA.—Salt Lake Tribune, April 9: This mine has been employing a full force of men all through the month, and there is a large amount of ore ready for shipment. The average product has been about 40 tons daily, which compares favorably with the 30 tons of the month. If transportation for the ore could have been obtained. It is reported that another large body of ore has been struck many ft. below the lowest level, of a quality equal to any other yet found, and in quantity greater than the immense body from which such vast quantities have been shipped.

FLAOSR FF.—This mine has been working a large force. The average production during the month has been about 50 tons daily, and it is proposed to increase the same to 100 tons. The mine appears to be as promising as ever. There is a large quantity of ore sacked at the mine, and the ore-house is quite full. Heavy shipments will commence so soon as the roads are in a condition to permit of transportation.

VALLEY.—This mine has a large quantity of ore on hand. The daily production has averaged 15 tons. The mine is working well, and the prospects are all that the owners could wish.

WELLINGTON.—The new discovery reported in our last month's summary has proved to be a large body of high grade ore, unquestionably a continuance of that in the upper levels. The mine has been working steadily, and a contract has been made to deliver 15 tons of ore daily for 60 days. A tunnel is being run to strike the vein 350 ft. below the out-crop. Over 3,000 sacks of ore are ready for shipment.

DAVENPORT.—The tramway belonging to this mine has been thoroughly overhauled, and is now in fine working order, and gives great satisfaction; 75 tons of ore can now be daily shipped by this means. The mine has greatly improved in appearance, and when all the necessary appliances and force are brought to bear, can be made to yield 100 tons daily. The number of workmen has been gradually increased through the month, and about 60 men are now employed. Large quantities of ore are being taken out, and the shipments during the month have been close upon 500 tons.

UTAH WINDSOR MINE CO.—This Co. owning the Halloway, Last Chance and Montezuma and Savage mines, continue a full complement of men, with the same satisfactory results as heretofore. Some 6,000 sacks of ore are stored and ready for shipment.

HOLLOWAY CREEK.—The main shaft is down 100 ft. and the vein is traceable all the way down. Work on a tunnel, to strike the ore at a great depth, is being prosecuted. The width of vein averages from 2 to 5 ft.

STOKER.—An incline shaft is down 180 ft., showing a body of ore all the way of great value. The vein varies in width from 1 to 4 ft.

THE MONTANA MINE.—This mine has been recently sold under an execution for \$11,000. The purchaser was Theo. F. Tracey, Esq., agent of Wells, Fargo & Co.

GLARIATION TUNNEL.—This tunnel is now in upwards of 470 ft. The character of ore has changed for the last 20 ft. it being now soft and decomposed and easily worked. The indications are that a body of ore is in close proximity.

MOMO MINE.—Cor. from Dry Canon to Utah Mining Journal, April 12: The main incline on this mine is now down to the depth of 380 ft., and shows mineral the entire distance run. At present the company are working a force of from 25 to 30 men, and have about 150 tons of ore on hand, in the ore-house, and at the mouth of the canon. This ore is of higher grade, on general average, than any taken from the mines of other sections within the limits of the Territory.

Several hundred thousand dollars are visible to the naked eye of any practical miner, who chances to pass through the mine, and this may account, in a measure, for the lucky owners not being over anxious to sell out.

LUEN MINING DISTRICT.—Salt Lake Tribune, April 12: Teocoma.—On Teocoma Hill are the Rising Sun, Settling Sun, Morning Star, and several other good mines. It is from these mines that Buell obtained his ore to supply his furnace, and the quality of them can be judged from the fact that with one small cupola, and inside of 4 weeks, Buell ran out 185 tons of bullion, that sold for over \$28,000 and this, too, without flux of any kind.

This extraordinary success may be accounted for from the fact that all ores of the Luen District contain a sufficient quantity of soft oxides of iron to answer for flux.

Again, the mines are nearly all located in limestone formations, passing at times into magnesia, or dolomite rock, with now and then traces of harytes (heavy spar) and fluor spar. With these ingredients of course no flux would be needed. The Buell furnace was but one cupola and that a very small one, yet from these ores without a particle of flux, were run out 11 tons in 1 day, valued at about \$165 per ton. There are at least 2,000 tons of this same class of ore now on the dump at the Teocoma mine alone. It is a lead ore, with but little sulphuret (galena) in it, but is mostly a mixture of grey carbonate of iron and small quantities of iron sulphides. These ores, as well as many others in the district, are said to contain the elements of lead. This mine has been extensively worked, and presents at a depth of 200 ft. a very large, regular and even lined fissure vein.

COOPER HILL MINES.—A group (the Elmer, Ironpole, Cherokee, Chortaw, Natchez, Waddell, Eureka, and some others). These are among the first mines discovered in the Luen District, and have been worked since 1859. The Elmer is a lead mine, 40 ft. deep, with a vein 12 ft. wide of solid ore between walls, yet at present mixed with so much earthy substance as to make its average assays very low. Specimens, however, run up to 60 per cent. lead and over \$300 in silver.

CENTRAL PACIFIC MINES.—We pass southward to the Teocoma, and I should state that this upper hill is one of the hills on the main divide of the Luen range of mountains, from which we look down upon and across Salt Lake, and far away over the sage brush valleys of Nevada—we next come to the Central Pacific group of mines, owned by J. D. Andrews & Co. These mines have been extensively worked and present a huge mass of ore on the dump. I cannot state how much, but perhaps a thousand tons or more. The company as well as lead-smelting ores, and assays very high in both. Here I will state that the general formation of the district is that of limestone, at times passing into dolomite, and exhibiting very fair specimens of marble.

There is also, now and then, a streak of scientific porphyry, occasionally a ledge of quartzite, but only a little of this kind there are a few mines in the district that have a quartz gangue, and these are generally chlorides, and carry genuine horn-silver, a very fine specimen of which I brought here with me, but have forgotten the name of the mine from which it was taken. The grade of ores of this district is constantly increasing as the development progresses, especially of such ores as are rich in lead.

BINGHAM CANON.

VEASPAN.—This mine is reported to be opening up beyond expectation, the vein reached being some 4 ft. in width, of very fine grade and exceedingly well defined. Many experienced miners and others well versed in mineralogy have pronounced it to be a true fissure vein.

The Bingham Mining and Smelting Co. This new organization will be of immense importance in developing the placer mines of Bingham Canon, as it proposes to inaugurate a complete system of drainage, with a view of reaching the bed rock. The tunnel is already in 1,100 ft., and on its course will tap some of the best placer mines. By the means now being adopted the company will turn out to be a complete success.

The Mono mine has a shaft down 360 ft., and in the bottom the ore looks better than ever before. The Panacea looks exceedingly well as does the Noyes. The Belle Whitbur, Emporia and Mountain Chief make a favorable showing, and the Dexter, Utah Queen and Miami develop in a manner which shows them to be excellent prospects.

STAMP MILLS.—The Wyoming mill having proven a decided success it has been instrumental in inducing other capital to seek investment in a like channel. A twenty-stamp mill has been ordered for Diamond City. Another mill is in contemplation to be erected on the ground recently purchased by Mr. Hammer. When these new enterprises are completed there will be five stamp mills in the district aggregating about eight stamps.

CAMP FLOYD DISTRICT.—THE QUEEN OF THE WEST MINE.—This mine is reported to be doing finely, and the prospects most encouraging. An 8 ft. vein of yellow chloride has been struck. Ten men are at work and take out 20 tons daily. The width of the vein is said to be 35 ft. with no hanging wall.

New Incorporations.

MAONETA G. M. Co., April 14. Object: To work the ledges in Grass Valley, Cal., known as the Donahue and Ryan Ledges, in Mohawk Hill Extension of the Ophir and Price Hill ledges. Capital stock, \$200,000, in shares of \$100 each. Trustees—David Fry, Benj. Price, J. L. Ramsey, Chas. Beyer, F. G. Donahue.

IRA AND REORA LEWIS CO., M. Co., April 14. Location, Wallapai Mining District, Nevada. Capital stock, \$100,000, in shares of \$100 each. Trustees—F. R. Lewis, A. O. Morse, Wm. H. Smith, I. de St. Marina, John P. Lawson.

JOA QUARTZ MINING CO., April 16. Location: In Mud Springs Mining District, El Dorado county. Capital stock, \$300,000, in shares of \$100. Trustees—B. H. Numan, R. W. Thompson, R. R. Swain, S. W. Backus and A. D. Carpenter.

A COMPANY called the San Lorenzo Fruit Preserving Company has filed its certificate of incorporation in Sacramento, with a capital of \$50,000. This company to dry the surplus fruit produced in the vicinity of San Lorenzo, by means of the Allen Process.

Meetings and Elections.

THE ARIZONA AND UTAH MINING CO., have elected the following Trustees: D. Townsend, J. A. Pritchard, W. H. Sears, H. C. Kibbe and G. W. Fisher. Secretary, Joseph Maguire.

GIANT POWDER CO.—Trustees: Egbert Jndson, Henry Brickwell, A. Block, Geo. C. Bode, Geo. C. Hickox. Subequently, Geo. C. Hickox was chosen President and Henry Pichior, Secretary. The same officers were chosen for the Atlantic Powder Company.

THE MONTANA AND UTAH M. COMPANY.—April 14: Trustees—J. A. Pritchard, M. D. Townsend, W. H. Sears, H. C. Kibbe and G. W. Fisher; President, J. A. Pritchard; Vice-President, H. C. Kibbe; Treasurer, M. D. Townsend; Secretary, J. Maguire. The receipts of the year were \$63,000 (from assessments), and the disbursement \$49,500, leaving a balance of \$13,500 on hand.

CALIFORNIA STOCK EXCHANGE BOARD.—The California Stock Board commenced business in February, 1872, and has since been in active operation. Financially, the enterprise has been a success, and the Board has now in the treasury \$4,000, with no debts. The monthly sales for the year have been as follows: February, \$1,007,048; March, \$831,089; April, \$2,187,809; May, \$1,007,105; June, \$1,071,805; July, \$1,563,240; August, \$1,311,010; September, \$1,044,515; October, \$1,044,515; November, \$1,779,293; December, \$1,770,555; January, 1873, \$1,813,300. Total, \$15,651,196. At the annual meeting held on the 4th inst. the following names were re-elected officers for the ensuing year: President, T. J. L. Smiley; Vice-President, O. L. Weller; Oiler, Joseph Tilden; Secretary, W. W. Lawton; Treasurer, National Gold Bank and Trust Company.—Alta.

Iron and Coal in the North of Europe.

Official reports from Sweden tell of the increasing commercial prosperity of that country, in which prosperity the iron trade largely shares. The total amount of iron of all kinds exported from Sweden to foreign nations during the year 1871 was 214,350 tons, valued at £2,045,704. Of this amount 98,334 tons (worth £882,193) were exported to England; and it is interesting to note, in connection with the iron trade between Sweden and Great Britain, that, according to the official statistics it is one which has of late years gradually increased. The various kinds of iron taken by Great Britain from Sweden bore the following proportion to the whole quantity of each exported:—Pig iron 58 per cent; bar-iron, 43; casting 65; and scrap, 54 per cent. In Sweden the manufacture of railway rails has never been much developed, and it is at the present time limited in extent, its commercial importance being small. There are only two works of any pretensions in operation, and good authorities concur in the opinion that there is a capital field for enterprise in Sweden in respect to the manufacture of these rails. It is believed that the toughness and good quality of Swedish iron render it well adapted to withstand the wear and tear to which rails are necessarily liable. The chief articles of import into Sweden are machinery, coals, etc. Of 22,494,487 cubic feet of coal which entered Sweden last year, 22,000,000 came from England—principally Davison's West Hartley and Cowper Hartley—while the greater part of the remainder was derived from Holland and a small quantity from Belgium and Germany. A good deal of machinery is also imported from England into Sweden, and this is an importation which is constantly increasing.

The discovery of coal in Scandinavia has been the subject of much observation, but it is generally believed that, unless the existing extraordinary high prices are maintained in this country it is not likely to effect the market much—the less so as the quality of the seams hitherto brought to light is inferior to the British article. Seams of coal, according to a Copenhagen correspondent, have been discovered in the south of Sweden, and several companies have been or are being formed to work them. One of the companies commenced operations on 21st January, under the direction of an English engineer. A circulation has been issued by Stockholm capitalists for the formation of a company to work the mines near Engelholm, to the south-west of Scania, where the operations referred to above are being carried on. The capital is fixed at nine millions of Swedish crowns, which has been mostly subscribed. An Anglo-Swedish society has been formed in London to purchase for £190,000, 7,000 acres of coal country in Scania. Borings for coal have also been made in Denmark, but without success. In the Island of Bornholm the precious mineral has been found, but the quality is inferior, and it has not yet been exported. A Dano-German company is being formed to make more extensive experiments. There are coal-beds in Jutland, and the search for new mines is being prosecuted in the island of Faere.

Diving Armor for Miners.

It sometimes happens that mines have to be abandoned and cannot be worked, either because of their filling with water, or on account of the large amount of foul air. To pump out the former, and to expel the latter, may be too expensive, or occasion too long a delay, and, hence, it has been proposed to educate a corps of diving miners to enter, and, if need be, to work such mines. For this purpose, a diving-school has been instituted at a coal mine in Saarbrück, Germany, where strong, healthy men of medium size, are first taught the construction of the armor, how to take it apart, and put it together, how to repair it, and all other details connected with it. They then descend into a large tank, where the water is but twelve or thirteen feet deep, this depth being sufficient to give them practice with the apparatus, and to accustom them to remaining under water. A new beginner, after two or three descensions, acquires sufficient knowledge to enable him to help himself under any circumstance, and is able to remain there half an hour. A squad of seven to nine men work together, and, while one is in the water, a second works the air-pump, a third holds the signal line, a fourth attends to letting out or taking in the hose that supplies air, and so on, each assisting in some way.

Practice with the armor in fire damp and irrespirable gasses, is obtained in tightly closed rooms, filled with gas, steam, and smoke, so that a person not in armor could not remain there at all.

After gaining practice in the shallow basins, they descend into the shaft of a mine, which is nearly 350 feet deep, and filled within eighteen feet of the top with water. At depths of thirty and sixty feet, are permanent stagings, where the diver may stop and rest. At a depth of ten to eighteen feet, almost all experience a peculiar roaring in the ears, or a tickling of the drum of the ear. This disappears as they descend farther, and all feel so comfortable in the water that they are able to stay there several hours without fatigue. While in the mine, the men practice various kinds of work, either in the dark, or by the use of a submarine lantern. Thirty men have already been instructed in the Saarbrück mine, and will be employed principally in drilling others to the same new profession.—*American Artisan.*

Flower Studies.

The attention of nurserymen and florists has been directed of late to the many beautiful shrubs which belong to the Flora of California. One of these, rarely found in gardens, is just passing out of bloom, the *Garrya*—so named by David Douglass, in compliment to a distinguished officer of the Hudson Bay Company. It was regarded as the greatest curiosity sent home by the great botanist and explorer, and the structure of the flower is so unlike anything else in the vegetable world that it forms a natural order all by itself. From a shrub of medium size, somewhat straggling in its growth, with ovate or roundish leathery leaves, there depends early in January long strings of pale silver green blossoms; looking precisely like strings of lilac or jessamine flowers upon a blade of grass. It looks as though nature had made it in some mood of play, and the form had become fixed without her intention. More curious than beautiful, once seen, it will never be forgotten. (See Illustration.)

Highest on the list of flowering shrubs we place *Manzanita*, lovely in name as in form and foliage. There are several species, and all are

THE GARRYA.

desirable additions to ornamental grounds. The evergreen leaves and richly colored stems remind one by a subtle association of the aboriginal inhabitants, who used their berries as food and the wood for many purposes in their simple arts. *Manzanita* is a social shrub, and enjoys having companions of her name and lineage within speaking distance, as you will see if you ever visit the petrified forest near Calistoga, over the ruins of which a family circle of *Manzanita* trees, of all sizes and ages, but with garments cut by an exact pattern, appear to have convened to study out the mystery. On the summits of the Sierra Nevada, where the vegetation is dwarfed by the cold, miniature trees of the *Manzanita* closely resemble the vegetable monstrosities which the Chinese and Japanese create by artificial methods.

Along the cañons the currant gooseberry (*Ribes sanguineum*) hangs pale, pink tassels upon delicate willow stems, and the Moose Wood (*Dirca palustris*) is covered with leaves of freshest green. Its blossoms, tiny yellow bells on leafless boughs, have just faded. This plant shows well the advantages of our climate, for it is now budding in the Alleghanies, and two months hence will open on the edge of the Maine woods.

High up in the chapparal of the foothills the earliest of the *Ceanothus* family is opening its tiny chalice, and filling the air with fra-

grance of lilac and birch, or, as some will have it, of the best green tea. Its racemes of countless flowers, so purely, delicately blue, as to seem more like a deeper atmosphere than anything else, cover the nakedness of rugged spiny branches, and change the chapparal into a haze of lovely color, lasting for many weeks. No single genus gives such beauty to the drapery of the hill as the *Ceanothus*. Varying from purple to pure white, and in season until past midsummer, inhabiting the deep woods and more open spaces, it is our constant, changeless friend. To complete the catalogue of its virtues, let us say that it takes kindly to civilization.

One of our most desirable shrubs is the evergreen cherry (*Cercas ilicifolia*). The leaf is more polished than the English Holly, more delicately carved at the edges, and the habit of this plant quite as massive and compact. It is the best hedge plant for our climate, though of slow growth, for the gophers and squirrels understand its medicinal properties, and wisely let it alone. A hedge of this cherry, growing on Mr. Wheeler's farm, near San Mateo, is the most perfect we have ever seen. It is twelve feet in height, about fifteen years old, and perfectly impenetrable to man or beast. At San Lorenzo it may be seen at the Llewellyn place in great luxuriance.

The *Amelanchier*, commonly called "Shad bush," or June Berry, is distributed through the entire country, from ocean to ocean. It deserves cultivation from its graceful, drooping

The Gold and Silver Yield of Montana.

The following article, from the forthcoming Report of the United States Commissioner of Mining Statistics, has been published in the *Engineering and Mining Journal*:

The collection of the mining statistics of this Territory, for 1872, I have entrusted to Mr. William F. Wheeler, of Helena, Montana, whose extensive acquaintance in the Territory has enabled him to send me detailed estimates of the product, and, considering the means at his command, very full data in regard to the several districts. His estimates of the yield of gold and silver of Montana, for the year 1872, are derived from shipments by express, from purchases made by bankers, brokers and merchants, and from miners and others, who have not shipped by express, and who have given him what they believe to have been the yield of their several mining districts.

Gold shipped by Wells, Fargo & Co. \$3,471,395
Gold from Missoula, by "pack-train," to Walla Walla 200,000
Gold taken out of the country in private hands, overland and down the Missouri 1,500,000
Gold retained in hand by miners for winter expenses 550,000

Total gold \$5,721,395

SILVER.
Refined silver bars shipped by express \$97,944
220 tons base bullion, shipped by wagon by Corinne, value \$500 per ton 110,000
60 tons base bullion, shipped East, via Fort Benton, at \$500 per ton 30,000
410 tons silver ore, shipped by wagon to Corinne, value \$200 per ton 82,000
135 tons of silver ore, shipped East—75 tons via Fort Benton, and 60 tons by wagon to Corinne—value \$200 per ton 27,000
Value of copper ore shipped for assay 5,000

Total coin value \$6,073,339

The foregoing estimate is accompanied with the following certificate from leading citizens of Montana, which refers to the estimate for this previous year also:

The undersigned, citizens of Montana, have examined the data upon which the foregoing estimates are based, and are satisfied that Mr. Wheeler has made a very moderate statement of the gold and silver yield of Montana for the year 1872. We have also examined the report for 1871, and consider his estimate of \$8,050,000, as the yield for that year of gold and silver from the mines of Montana, as very correct.

D. C. Corbin, Cashier of the First National Bank, Helena.

T. H. Kleinschmidt, Assistant Cashier, do.
George W. Fox, of Fox, Lyster & Roe, Bankers.

L. H. Hirschfeldt & Bro., Bankers.
R. E. Fisk, Editor of the Helena Herald.

D. S. Wade, Chief Justice.

I am confident that the above estimate is largely under the actual yield.

S. T. HAUSER, Pres. First Nat. Bank.

*In regard to this item, Mr. Wheeler says: "I have taken the actual shipments by 'express' of gold dust and refined silver bars. But I find by inquiry of the several banks and brokers that they have purchased nearly half a million more than the amount reported shipped by express in the Territory. The contracts of the banks in the Territory with the Express Company begin with May 1, 1872, and end with May 1, 1873. The bankers all say they will be able to fulfill their contracts, as they have four months to make shipments in; therefore, the amount will have to be furnished from the yield of 1872, and I am thus justified in adding that sum to the amount named as the yield for 1872 in my report, which will make the total yield of the Territory for 1872 upwards of \$7,000,000."

[I quote the above statement, without adopting the suggestion, since it seems to me that there would be no fairness in adding the first shipments of 1873, on the ground that they contained product of 1872, to an aggregate which, by the same reasoning, must contain a part of the product of 1871. I have, therefore, retained the original figures, representing simply the shipments of 1872.—R. W. A.]

On this point Mr. Wheeler says: "Towards autumn, after the season's work in our placer mines is done, large numbers of miners go to Utah, Nevada and California, to seek employment for the winter in the numerous silver and gold quartz mines there, and return in the spring to their placer mines here. They generally go in companies of ten to twenty, and carry with them the product of their past summer's work, in order to avoid 'express charges,' which are from two to three per cent, and for mutual protection. The sums they take away are large in the aggregate, and the express company is the least likely to know the amounts, in the case of travelers by the coaches, since the express company assume to charge for all gold carried by passengers in this way. Many passengers in the stages take from \$1,000 to \$5,000 with them secretly, to avoid paying these express charges. I know of one company of miners, who traveled by their own conveyance, and took out last fall \$60,000. I doubt if I have sufficiently estimated the amount thus taken out by a quarter of a million. Much of this gold is sold in Utah, Colorado and California, and is deposited in the mints at Denver and San Francisco, and is not reported as the yield of Montana."

Mr. Wheeler says: "There are, to my own knowledge, more than 3,000 tons of silver ore lying on dumps at the mines, and waiting for purchasers, or for spring to permit shipments, etc., of which I have made no account. This cannot properly be included, the value being uncertain, and the amount, whatever it is, is sure to find a place in the aggregate for a succeeding year."

RICH SPECIMENS.—Frank Helling, of Gold Mountain, a few days since exhibited to us one or two of the finest specimens of gold ore that we have seen for many a day. They were selected pieces from the Golden Leaf, a claim belonging to Roth, Smith & Helling, and were literally loaded with lumps and flakes of gold. The ledge is from 2½ to 3 feet in width, all the ore being of a very high grade. It is stated that the Manhattan Company of Austin under the Presidency of Mr. Taylor, are about to build a mill at a point some two miles from the principal mines, where water can be readily obtained by sinking.—*Inyo Independent.*

habit and early bloom, though less valued by us than it is by our friends in the Eastern States, as a harbinger of spring.—*Illustrated Press for March.*

STOCKHOLDERS AS CREDITORS.—An important point arising out of the bankruptcy of the Kearsarge Mining Company has gone before three tribunals; and before all three, judgments have been rendered in one way. The Treasurer and Superintendent of the Company are large stockholders, and they presented claims for money advanced by them. The question was, whether they should rank as ordinary creditors or should have their claims postponed to those of other creditors who are not stockholders. Successively, Register Clarke, Judge Hoffman and Judge Sawyer have affirmed that a stockholder who is a creditor can share coördinarily with other creditors in the distribution of the assets.—*Call.*

The Blue Mountain Coal Company have received a lot of implements for constructing a railroad from the Coquille river to the navigable waters of Coos Bay. The length of the road is eight miles. The company intend to have the road in running order this summer.

A VALUABLE deposit of copper has just been discovered in Montana. The ore is described as very rich and remarkably abundant.

USEFUL INFORMATION.

Magic Paintings.

It is a fact well known to chemists that many salts undergo change of color when heated. Sometimes this is due to the loss of water, at others, it is due to a change in the molecular condition of the surface.

The red sulphide of mercury, known as cinnabar, turns black when heated, and its original color returns on cooling. For this reason, it has been proposed to use it for painting journals and journal boxes, not easily accessible, but in plain sight. The change of color would indicate a "hot box."

The salts of cobalt are so sensitive to slight changes of temperature that they have long been used as sympathetic inks. By writing on white paper with a dilute solution of chloride of cobalt, the writing is invisible until the paper is warmed.

The beautiful red iodide of mercury becomes yellow when heated; the yellow iodide of silver and mercury becomes orange red; and the scarlet red iodide of copper and mercury turns a deep black. By judicious selection and arrangement of these colors very striking effects are produced on warming. A bunch of half-ripe blackberries, for example, if painted red, instantly ripen to a deep black; red roses become yellow, and yellow lemons turn into deep colored oranges.

A winter landscape may be painted in such a manner, that, when warmed, it is converted into a summer landscape. The white sky, painted with chloride of cobalt, becomes blue when heated; the grass and foliage on the trees are palated with chloride of cobalt and nickel, which turns green when heated; the berries and red flowers are colored with dilute nitrate of cobalt solution, and appear red when heated; for the blue flowers, a solution of pure acetate of cobalt is employed. The outlines of the picture, as well as those objects, which, like houses, trunks, and branches of trees, etc., are to remain of one constant color, are painted with the ordinary water colors.

How Gas was First Introduced.—It is now sixty-six years since Pall Mall, London, was lighted with gas—the first street of any city so illuminated. The idea of using carburetted hydrogen gas for purposes of illumination first occurred to Wm. Murdoch, Ayrshire, Scotland. He made his first experiments in 1792, and six years later he succeeded in lighting up the engineering works of Watts & Boulton, at Birmingham. Murdoch was a sagacious man, worthy to be associated with Watt. The merit of bringing gas light to London, however, he loans to a German named Winsor. He was an enthusiast, and employed all the arts of quackery and fanaticism to convince the benighted Londoners of the merits of his scheme. Sir Walter Scott did not believe in this German genius, and actually called him a madman; and even the liberal mind of Sir Humphrey Davy failed to take in the idea that gas was applicable to purposes of lighting houses and streets. Winsor, however, stuck to his business; he won supporters; and one night a long line of streets litized out in a burst of gas lamps, much to the astonishment and admiration of the citizens. After such a demonstration, the promoters were no longer considered idiots. It is calculated that \$100,000,000 are now invested in gas manufactures in Great Britain.

NEW METHOD OF MAKING HYDROGEN GAS.—We have to report the invention of making hydrogen, invented by Gifford of Paris, and claimed to be so cheap as to cost only 10 to 30 cts. per thousand cubic feet, therefore less than one tenth of our common coal gas. The *modus operandi* is not given, and therefore it is impossible to verify the statement in regard to the expense. But if it is true, it will no doubt create a revolution not only in gas matters, but in the cooking of food, in metallurgy, in the working of metals, and especially those of a refractory kind, as platinum and others. In the method now referred to, the gas is said to be produced by a very rapid decomposition of water, and we are anxiously awaiting the details.

AMOUNT OF WATER IN THE ATMOSPHERE.—Did you ever think how much water is in the air, floating unseen? It generally amounts to nearly three gallons above each foot of the earth's surface, and often much more. As new vapor is always rising, the amount of rain that falls during a year is very large. At one place in the Himalaya mountains as many as three hundred inches deep fall in twelve months, or enough if it all fell at once to cover the land with water twenty-five feet deep. In San Francisco thirty-five to forty-three inches fall annually. In the Sierra Nevada the annual fall is from five to six feet.

TO DETECT ADULTERATION IN INDIA-RUBBER.—One criterion for good rubber has been that it would float on water, its specific gravity being .985. The addition of any mineral adulteration, of course, renders it heavier than water, and it sinks; but, recently, cork has been introduced as an adulteration, and, as it injures quality, without increasing its weight, specific gravity becomes an insufficient test of quality. In some specimens examined at a chemical works in Stolberg, forty to fifty per cent. of mineral constituents were found, and to these were attributed the fact that india-rubber finds less use in the arts than might be expected.

East Indian Method of Cleaning Silver.

The Boston Journal of Chemistry, gives the following interesting account of the way in which the natives of East India clean silver articles.

The East Indian jewelers never touch silverware with any abrasive substance. For all articles of the kind, even the most delicate, the method of cleaning they adopt is as follows: Cut some juicy lemons in slices; with these rub any large silver or plated article briskly, and leave it hidden by the slices in a pan for a few hours. For delicate jewelry, the Indians cut a large lime nearly in half, and insert the ornament; they then close up the halves tightly, and put it away for a few hours. The articles are then to be removed, rinsed in two or three waters, and consigned to a sancepan of nearly boiling soapuds, well stirred about, taken out, again brushed, rinsed, and finally dried on a metal plate over hot water, finishing the process by a little rub of wash-leather (if smooth work). For very old, neglected, or corroded silver, dip the article, with a slow stirring motion, in a rather weak solution of cyanide potass.; but this process requires care and practice as it is by dissolving off the dirty silver you obtain the effect. Green tamarind pods (oxalate of potash) are greater detergents of gold and silver articles than lemons, and are much more employed by the artisan for removal of oxides and fire-marks.

A Perfect Waterproof.

A writer in an English paper says: By the way, speaking of waterproofs, I think I can give travelers a valuable hint or two. For many years I have worn india-rubber waterproofs, but will buy no more, for I have learned that good Scottish tweed can be made entirely impervious to rain, and, moreover, I have learned how to make it so; and, for the benefit of your readers, I will give the recipe:

In a bucket of soft water, put half a pound of sugar of lead, and half a pound of powdered alum; stir this at intervals, until it becomes clear, then pour it off into another bucket, and put the garment therein, and let it be in for twenty-four hours, and then hang it up to dry without ringing it. Two of my party—a lady and gentleman—have worn garments thus treated in the wildest storms of wind and rain, without getting wet. The rain hangs upon the cloth in globules. In short, they were really waterproof. The gentleman, a fortnight ago, walked nine miles in a storm of rain and wind, such as you rarely see in the South; and, when he slipped off his overcoat, his underwear was as dry as when he put them on. This is, I think, a secret worth knowing; for cloth, it can be made to keep out wet, in every way, better than what we know as most waterproofs.

KILLING ANIMALS WITH CHLOROFORM.—Many persons would be glad to know how to kill an animal without suffering, and we venture to give this benefit of our experience. We are constantly called upon to destroy horses, dogs and cats, and have little difficulty in doing it. For horses we use a large sponge, say six inches in diameter, thoroughly saturated with chloroform, which is dropped into a bag, large enough to be drawn over the horse's nose. It is not desirable to have the bag "air-tight;" for, if so, suffocation is likely to ensue. In two or three minutes the horse is unconscious, and in eight or ten minutes dead, without suffering. For dogs and cats, a similar process, using a small sponge and bag; or these animals, with the saturated sponge, may be put in a box admitting some air, when they soon "go to sleep." Seventy-five cents worth of chloroform will kill a horse, and twenty-five cents a dog or cat. If one saturation of the sponge does not complete the work, repeat it.—*Our Dumb Animals.*

ARTIFICIAL ORGANISMS.—The researches and experiments into the artificial formation of organic substances are being pursued by many original experimenters, with most encouraging success, and bid fair at an early day to reach a much greater practical value than has yet been realized. Although the methods adopted by the chemist in their artificial compounds are different from those which Nature employs; there can be but little doubt that the forces brought into requisition in both cases are identical. The conditions, however, under which the two operators work, are widely different. There is evidently a wide field for important research in this direction.

FLIES have immovable eyes. They stand out from the head like half an apple, exceedingly prominent. Instead of being smooth hemispheres, they have an immense number of facets, resembling old-fashioned glass watch seals, each one directing the light directly to the optic retina. That explains why they cannot be approached in any direction without seeing what is coming.

A CHEAP AND HARMLESS HAIR DYE may be made of the extract from the green epicarpium of walnuts. The effect of the juice of this substance in blackening the skin is well known. It is perfectly harmless in its effect on the skin or scalp.

GOOD HEALTH.

Health of Women.

Farmers' wives are not as healthy and red-cheeked as city people suppose them to be. In a journey of a hundred miles, you may see a few rosy, bright-eyed, happy women; but, as a rule from Maine to California, care-worn faces, sunken eyes and compressed lips, tell pitiful tales of disturbed rest, of weariness and suffering. We do not attribute this to the tyranny of husbands. We have yet to see the man who does not pity his sick wife.

It cannot always be attributed to the tyranny of fashion, thousands of those suffering women do not read fashion-books. We do not propose to point out all the causes that operate so destructively, but will attract attention to a few not generally attended to by patients and physicians.

We speak of women who at marriage gave promise of a vigorous, healthy life, but as the years passed, their hopes faded like the haseless fabric of dreams.

Asking questions, and closely observing their habits, we learn that very soon after marriage the regular bath was omitted. "I knew it would refresh me, but it was not convenient. I had company, or was tired; and put it off from time to time, until the bath ceased to be a regular habit, and is now only the occasional luxury." The result was, the waste matter, that should have been passed off by the skin, had to be carried along, to be cast out by the kidneys and bowels; or was retained in the blood, loading the breath with impurities and finally clogging the liver.

Here, we have, through neglect of the bath, overworked kidneys, constipated bowels, and a torpid or tired liver. The vital forces ever working to preserve life, and the machinery of life, tossed out flags of distress. Yellow flags, over tongue, skin and eyes; and finally took away relish for food. The wise woman would have "abstained from food" and exhausted labor, and would have taken a thorough rubbing, scrubbing, sweating-bath, to open the pores. Before going in and while in, and after coming out of the bath, copious drinking of water to wash the blood would have assisted the vital forces to go on with the cleansing processes.

"How?"

In this way: Water is very rapidly absorbed, or taken into the circulation. Then, to speak very plainly, it dissolves dirt; and through the skin, kidneys or bowels floats it out of the body.

Every particle of worn-out matter, salts, or medicines, dissolved and carried through the natural channels, by so much relieve the tired liver; when rested it will resume work without spurs or whips of any kind.

Sick women have not thus reasoned; have not thus been obedient to the Divinely appointed law of cleanliness.—*Science of Health.*

Curing Without Medicine.

What is disease, let us ask again, that it should or should not be cured? This solution of the question underlies all argument, all theory, and all practice. It involves the truth or falsity of every medical system. Those of our readers who patiently and carefully follow the series of articles appearing monthly in our columns to its conclusion, will have all the data before them by which to settle this vitally important question, which have accrued from two thousand years of assiduous study and experimentation. We hope and trust that the testimony will be conclusive in establishing the right system, whatever that may be.

Meanwhile, as an aid to the study of this problem, as well as a key to its solution, let us take the simplest illustration possible. Give a well person an "operative dose" of medicine, no matter what. It may be a compound of Bergh's and Bonner's remedies for "hippohorrea"—tincture of iron, Jamaica rum tartar emetic and nitre. In an hour or two the person will be sick. He will experience nausea of the stomach, griping of the bowels, dizziness, headache, debility, and perhaps vomiting and purging. The disease is the effect of the medicine. It is the effort of the system to expel the medicine. Is this effort to be cured, or is the patient to be cured? Clearly the effort, the disease should rather be promoted than suppressed, that the drugs may be removed from the organic domain. The true medication is to regulate the effort so that it will be successful in its work of purification. To cure it with more drugs is simply warring on vitality adding insult to injury.—*Science of Health.*

MILK AS A MEDICINE.—An interesting article recently appeared in the London Milk Journal, concerning the value of milk as a remedial agent in certain diseases. Several physicians of high standing regard it as a specific for diarrhoea, dysentery, and incipient cholera. The milk should not be boiled, but heated sufficiently to be agreeably warm. It is also recommended as of great value in typhoid fevers—as cooling and nourishing, and as promoting sleep.

AVOID FERMENTED FOOD.—Fermentation of food should always be guarded against as the warm weather approaches. Cooked vegetables, fruits, beans, etc., when set away are very liable to ferment. Instead of warming up cold messes, thoroughly scald them. Much sickness is caused by eating stale food.

MISCELLANEOUS.

Cleaning Feathers.

How shall we renovate old feathers, and also clean old ticks? This inquiry I have seen in the papers. My way is this: When the weather portends a heavy shower of rain, I lay the feather tick on clean grass, or in some other suitable position, and smooth it over evenly. One-half hour's heavy rain will clean one side of a badly soiled tick, unless there be greasy spots. In this case I take a pail of hot suds, pour it on the spots, brush them, and let the rain rinse it out. I then turn it over and serve the other side the same. If the shower should be of short duration, I put the bed out in the next rain.

To dry the bed, lay up the tick on slat work, clean rails, or something of the kind. If the feathers are much wet, so much the better. When drying, shake up, beat with light rods, pick up lumps if there be any. When the bed is dry, the tick will be clean, and the feathers almost as good as new. Some of our beds have been used thirty years. I have lain them in the rain every summer; they are now clean and good. It takes but a short time to dry the bed, but when it is dry to appearance, it is not at all fit to sleep on, but should be laid on an empty bedstead, a month or more, with the windows up. This caution may be unnecessary, as no wise head sleeps on feathers in the summer.

As for the labor, I had rather clean five beds in the rain than one in the way generally recommended—that is by poring the feathers from the tick on a sheet in an empty room (when there is no empty room in the house), washing the tick, stirring up the feathers thoroughly, returning to the tick, and laying in the sun for several days, turning and beating up often.—*M. D. E., in Western Rural.*

COOKING VEGETABLES.—Why should vegetables be washed in warm water first, then cold, to clean them from the sand and insects? The hot water, which must be hotter than tepid, causes the insects and sand to fall out at once.

Insects do not always dislike cold water and salt, but hot water kills them.

It must be understood that only a small handful of greens or one head or cabbage at a time must be washed, and then instantly thrown into cold water, which crisps and thoroughly cleanses them. Spinich, leeks, celery and asakale, are thus rendered very clean, and, moreover, are very rapidly cleansed.

It is worse than useless to attempt to cleanse vegetables in salt and water. The hardness which salt creates in the water prevents all cleansing properties. The salt may kill the insects (it does not always do this), but they stick on hard and fast; the hot water makes them fall out at once, and the cold water crisps and also bleaches the vegetables.—*Mrs. Warren.*

COOKING PEAS.—No vegetable depends more for its excellence upon good cooking than peas. Have them freshly gathered and shelled, but never wash them. If they are not perfectly clean, roll them in a dry cloth; but this is seldom required, and then only through carelessness. Pour them into the dry cooking dish, and put as much salt over them as is required; then pour on boiling water enough to cover them; boil them fifteen minutes if they are young; no pea is fit to cook which requires more than half an hour's boiling. When done, put to a quart of peas three tablespoonfuls of butter, and pepper to your taste. Put all the water to them in which they were boiled. The great mistakes in cooking peas are in cooking too long, and in deluging them with water.

RANK FLAVOR IN MUTTON.—A correspondent of the Rural New Yorker, writing from New Mexico, suggests that the rank flavor in mutton may not be due either to the wool or the entrails; but possibly to the breed, management, and more particularly to the feed of the sheep. Mutton, particularly in the summer months, is used extensively in New Mexico as an article of food, and is free from rank flavor, though hatched in the usual way; and it tastes no more like that of the East, than Buffalo does like short-horn beef.

We may say the same of California raised mutton.

LEMON CHEESE CAKE.—A quarter of a pound of butter, a quarter of a pound of sugar, a wine glass of milk or cream, two ounces of sponge cake, three eggs, the grated rind of one and juice of half a lemon; slice the cake and pour over it the milk or cream; beat the butter and sugar together, and stir into it; mash the sponge cake very fine, and add to the above; grate the yellow rind, and squeeze the juice of half a lemon and stir in. Cover the pie plates with paste, fill with the mixture, and bake in a moderately hot oven.

AN ARTIFICIAL OYSTER.—Where will the genius of the American inventor end? A down east journal informs us that a Maine man is about to apply for a patent for an artificial oyster made out of flour paste, tapioca, salt and water. The inventor places these in second hand oyster shells which are carefully glued around the edges; and when a half intoxicated customer calls for a dozen raw on the half shell, he gets them fresh from the shop.

Legal Tender Rates.—S. F., Thurs., April 17—buying 86; selling 87.

Table of Contents.

GENERAL EDITORIALS.—Death of an Inventor; Mining Suits; Utilizing Water Power, 241. Decisions of Interest to Miners; Geology of the Stars, 243. Narrow Gauge; Patents and Inventions, 249. **ILLUSTRATIONS.**—First View of the Sierras, 241. The Garrys, 246. Improved Door and Gate Hinges, 249.

CORRESPONDENCE.—A Rambler's Ride Over Rough Roads; The New York Money Market—Threatened Trouble Ahead, 242.

MECHANICAL PROGRESS.—Air Power; Nov. aculite; High Pressure Steam and Compound Engines; American Machinery in Europe; Interesting and Valuable Discovery; Early Saws; Car wheels and Axles, 243.

SCIENTIFIC PROGRESS.—Progress in Chemistry; Synthesis of Acetic Acid; The Polar Exploring Expedition; Impact of Balls; Wood and Coal Ashes; A New Fuel; Scientific Association; The Temperature Above the Clouds; Volatilization of Iron; To Detect Cobalt in Silk Fabrics, 243.

MINING SUMMARY.—From various counties in California, Nevada, Montana and Utah, 245.

MINING STOCK MARKET.—Table of Daily Sales and Prices and Comparative Prices for the Week; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 244.

USEFUL INFORMATION.—Magic Paintings; How Gas was First Introduced; New Method of Making Hydrogen Gas; Amount of Water in the Atmosphere; To Detect Adulteration in India-Rubber; East Indian Method of Cleaning Silver; A Perfect Waterproof; Killing Animals with Chloroform; Artificial Organisms, 247.

GOOD HEALTH.—Health of Women; Curing Without Medicine; Milk as a Medicine; Avoid Fermented Food, 247.

MISCELLANEOUS.—An English View of Our Iron Trade; Westinghouse Brake on Driving Wheels, 242. Iron and Coal in the North of Europe; Diving Armor for Miners; Stockholders as Creditors; The Gold and Silver Yield of Montana; Rich Specimens, 246. Cleaning Feathers; Cooking Vegetables; Cooking Peas; Hot Flavor in Mutton; Lemon Cheese Cake; An Artificial Cynure, 247. The Disinfection of Lead; Diamonds in the Hydraulic Washings of California; The Gold Places of the Plains, 250. Patent Decision, 253.

LABOR SCHOOLS.—As we go to press, a meeting of the gentlemen selected by the Mechanics' State Council, to organize a Deliberative Assembly, is being held. They will effect an organization and elect an Executive Assembly. The question of labor schools is a very important one, and discussions of the subject by the gentlemen selected will be a great benefit.

COPPER.—Five or six copper ledges are reported as discovered on Church Island, in the midst of Salt Lake. Assays run up to 42 per cent. There is considerable excitement in mining circles.

PATENT EXTENSION.—The commissioner of patents has granted the application for the extension of a patent to Francis and John Stock, of San José, Santa Clara County, for pump boxes.

TR. in large quantities, is said to have been found at Walla-Walla. A dispatch from Portland, Oregon, states that twenty-six pounds of metal have been brought in.

CHINESE LABOR IN MINES.—It is stated that the Reed quicksilver mine in Napa County is employing a gang of Chinamen as miners, discharging whites in order to do so.

RICH.—It is stated that "49-diggings" have been found at Duck Creek, Montana, and there is a rush there from Diamond City and elsewhere.

THE PROCE Record, one of our most valued interior exchanges, has come to us in an improved and enlarged form.

COAL has been found on the ranch of Thomas Guinean, in Napa Co. The mine promises to be valuable, the deposit being large.

In the coal mines of Amador a vein of coal twelve feet in thickness has been struck in an incline lately run in the ridge between Lone and Jackson valleys.

Decisions of Interest to Miners.

In the issue of the MINING AND SCIENTIFIC PRESS of the 5th inst., we gave the recent Act of Congress which extended the time for the first annual expenditure on claims located prior to the passage of the Act of May 10th 1872, to June 10th, 1874, and now have several other matters of interest to the mining community. The first is a rather interesting and important question coming before the Commissioner of the General Land Office from the Carson City Land Office, which was decided on the 11th inst. The Dardanelles Mining Company having applied for a patent for certain mining property alleged to be a continuation of the Bosphorus lode, the Overman Company made an adverse claim to the same mine as a continuation of the Comstock lode. The Dardanelles Company moved to dismiss this adverse claim, and Commissioner Drummond now decides the motion cannot be granted, holding that there is no law or instructions of the department authorizing such motions to be made or granted; that the only mode of bringing a matter of this kind before the General Land Office is to take an appeal from the decision of the Register and Receiver when made.

Another decision of the Commissioner of the General Land Office is of interest as showing that the provisions of the law of May 10th, 1872, are to be strictly adhered to. The case is in reference to the Lady Morehead mine in Little Cottonwood Cañon, Utah. The title of the case is A. G. Paddock vs. John P. Taggart. Paddock's adverse claim to the mine, as a continuation of the Elmer lode, was rejected by the Commissioner on the ground that no survey had been made of the Elmer claim within the sixty days required by law.

It will be remembered that the Mining Law states that after application for patent has been made, the notices posted, etc., the Register of the Land Office, upon the filing of the application, plat, field-notes, notices and affidavits, shall publish a notice of the application for the period of 60 days in the newspaper which is published nearest to the particular claim. The claimant at the time of filing this application or at any time thereafter, within the 60 days of the publication, must file with the United States Surveyor General a certificate that \$500 worth of work has been done upon the claim; that the plat is correct, with a description accurate enough to identify the claim, etc. At the expiration of the 60 days of publication he must file his affidavit that the plat and notice have been posted in a conspicuous place on the claim during said publication. If no adverse claim is filed during the 60 days of publication the patent is granted, on proper payment. The importance of attending to these details in the matter of location, labor and expenditure, is illustrated by this decision, and will be readily perceived when it is understood that a failure to give the subject proper attention, may invalidate the claim.

It has been also decided by the Commissioner that borax deposits may be located under the provisions of the new law, and as considerable interest is being taken in mining and prospecting for this substance it is well to bear in mind the restrictions as to the size of locations, which come under the provisions of the sections referring to placer claims. The twelfth section of the Act of July 9th, 1870, provides that no location of a placer claim shall hereafter exceed 160 acres for any one person, or association of persons, which location shall conform to U. S. Survey. The tenth section of the Act of May 10th, 1872, (the new law) provides that all placer claims hereafter located, shall conform as near as practicable to the United States system of Land Surveys, and no such locations shall include more than 20 acres for each individual claimant. The Commissioner's construction put upon these two sections is as follows:

The foregoing provisions of law are construed to mean that after the 9th day of July, 1870, no location of a placer claim can be made to exceed one hundred and sixty acres, whatever may be the number of locators associated together, or whatever the local regulations of the district may allow; and that from and after the passage of said Act of May 10, 1872, no location made by an individual can exceed twenty acres, and no location made by an association of individuals can exceed one hundred and sixty acres, which location of one hundred and sixty acres cannot be made by a less number than eight bona fide locators, but that whether as much as twenty acres can be located by an individual, or one hundred and sixty acres by an association, depends entirely upon the mining regulations in force in the respective districts at the date of the location; it being held that such mining regulations are in no way enlarged by said acts of Congress, but remain intact and in full force with regard to the size of locations, in so far as they do not permit locations

in excess of the limits fixed by Congress, but that where such regulations permit locations in excess of the max mums fixed by Congress as aforesaid, they are restricted accordingly.

A case is now pending on appeal before the Secretary of the Interior which is of great interest to miners, especially to those who are occupants of grounds on sixteenth and thirty sixth sections. A dispatch from Washington to the *Call* gives the substance of the whole matter. It appears that unusual professional and lobby influences are being brought to bear on the Secretary of the Interior, in the important case of the Keystone Consolidated Mining Company, the Original Amador Mining Company, the Bunker Hill Quartz Company, and the town site of Amador against the State of California. The purpose is to secure a reversal of the decision of the General Land Office so as to turn over to A. H. Rose and his associates property worth millions of dollars for which the nominal sum of \$400, was partly paid by Henry Casey, the alleged grantee from the State.

The case, according to the *Call's* dispatches, involves extraordinary features of apparent fraud, as well as a principle of utmost importance to thousands of mine owners. The mines in controversy are situated on the mother lode of California, and have been worked since 1850. A dozen years ago, Rose sold for \$130,000 the Keystone mine, which he now seeks to recover in the name of Casey and the town of Amador.

The town was founded in 1850. Its site and all these mines are situated upon the east half of section 36, township 7 north, range 10 east, Mount Diablo meridian. In 1870 certain parties procured a United States survey of that township, and it is alleged that they induced the Deputy Surveyor, by fraudulent field notes, to represent the mines and town as located upon the west half of the section. The purpose was to deceive the occupants, so as to induce them to apply for the wrong tract, while the speculators could, without opposition, purchase from the State for \$400 and receive a patent for the tract on which these properties are actually located. The fraud was discovered and exposed by abundant proofs, demonstrating unquestionably the surveyor's infidelity in returning as agricultural land the richest half section of mineral land ever discovered.

The patents having been issued, the bona fide mining claimants and town authorities immediately applied to the Land Department for patents under the mineral and town site laws, but the would-be purchaser from the State then boldly claimed that the School Land Act of March 3d, 1853, was a grant, in *presente*, of both the surveyed and unsurveyed and both the mineral and agricultural lands comprised in the sixteenth and thirty-sixth sections of every township and consequently that the mineral lands in controversy, situated in the thirty-sixth section, passed to the State immediately on the passage of the Act of 1853.

To this it is replied that mineral lands were excluded from the grant to the State; that the State title did not rest in any lands until surveyed, there being prior thereto no sections sixteen and thirty-six; that the Act of 1853 provided as to mineral lands; only township lines should be the rule, which provision was not repealed until July 9, 1870; that it was competent for Congress, before vested interests had been attached, to make a different appropriation of the lands; that before the survey, Congress did, by Act of July 26, 1866, make a different appropriation of the mineral lands. That if this were so, yet the particular tract in controversy was expressly excepted from the State grant, by the seventh section of the Act of 1853, by reason of its settlement and the erection of dwelling-houses there prior to the survey.

The local land officers and the Commissioner of the General Land Office decided against the pretensions of the private claimants, who use the State's name, and the case is now pending on appeal before the Secretary of the Interior.

The danger grows out of the fact that the Supreme Court of California has decided that the Act of 1853 did vest title to all sixteenth and thirty-sixth sections in the State prior to their survey; and though it is believed that the Court will grant a rehearing and reverse that decision, its action nevertheless lends color and support to the attempt now making to obtain possession of the Amador mines, and to establish a principle fraught with immense danger to thousands of other interests.

Several well known California lawyers are in Washington to assist in the prosecution. It is probable that dilatory tactics will be employed to postpone a decision on this tainted claim until the Benjamin Selling case from the Marysville District can be presented to the Secretary for a decision of the naked question of the right of the State to the sixteenth and thirty-sixth sections of mineral lands; so that if the right of the State is affirmed, it will be comparatively easy to find a pretext for deciding Rose's case in his favor.

The question has a vital importance to all mineral occupants of sixteenth and thirty-sixth sections. If the mineral claimants in either the Keystone or the Selling cases are defeated, then all mines upon similarly numbered subdivisions or which, upon future survey, may prove to be so numbered, are at the mercy of the first applicant to purchase from the State at \$1.25 per acre.

It is represented in Washington that the parties who initiated this speculation have already taken the requisite steps to file first applications for all similar sections throughout the State of California. The same dangers threaten mining occupants in every other mineral State.

"The Geology of the Stars."

The above sentence, which is the title of a little pamphlet before us, is eminently suggestive, and could not possibly have been thus used with propriety, until within the past ten or fifteen years. The telescope long since gave us a very correct idea of the grandeur and immensity of space, and of the fact that it was occupied by an innumerable number of suns and worlds, more or less resembling our own.

The researches of the geologist and the chemist have given us a very correct idea of composition and geology of the globs which we inhabit. Aided by such researches, improved telescopes have also been able to show that the moon is made up of elements similar in appearance, at least, to what we find on this earth, and that its surface is divided into valleys, plains and mountains. But what of the sun and what of the stars? The telescope fails to satisfy our enquiry as to them. True, the former appears to the telescopic view to be a vast globe of fire; but as to what supports that combustion or what may be the elements composing the sun and stars, it tells us nothing—and any such thing as a study of the "geology of the stars" has until quite recently been considered utterly beyond human power—one of the mysteries of nature, closed forever to the knowledge of man.

Such was the condition of astronomical science, when, that most wonderful of all scientific instruments—the spectroscope—was brought to the aid of the astronomer and geologist. This instrument developed the fact that light was capable not only of being separated into its primitive colors; but also, that under proper manipulation, it could be made to mark or superimpose upon those colors certain hands and lines, by which the identity of the element or substance which sends forth the light may be readily detected. These facts having been learned by experimenting with various substances in the laboratory, the light from the sun and stars, and from nebulae and comets was also submitted to its test with results equally satisfactory; and it is by this means that astronomers have of late years been actually studying the geology of the sun and stars. The progress of this study has demonstrated the fact, not only that the whole family of planets in our solar system has had a common experience or history; but that every body in the visible universe undoubtedly belongs to one system of matter.

It is definitely proven by the apetroscope that the mineral constitution of all the stars, comets and nebulae is similar to that of the earth. We have learned by it enough of the phases of matter to feel certain that our own system represents all the various progressive stages in the natural evolution of matter from its gaseous condition, as observed in the faintest comets or nebulae, to the completed, worn out, planetary condition exemplified in the moon.

The spectroscopes has fully verified the nebular theory that all matter was once diffused through space in the form of a vapor or fire-mist of a most attenuated state, which, under some special condition or creative act, became detached and divided into fragmentary portions, the contraction of which inaugurated rotation, which was inevitably accelerated until peripheral rings were thrown off, broken, and aggregated into planets.

Our sun, near "the beginning," occupied a sphere in space, whose boundary exceeded that circumscribed by the revolution about the sun of the most distant planet of our system—perhaps one even yet undiscovered. It has continued to throw off periphery rings until our whole family of planets has been produced, and then by such successive offshoots and contractions has at last come to occupy its present condensed form in the center of the system. Most of the planets, in their turn, following the same law, have thrown off smaller rings forming secondary planets or moons.

The most striking and instructive feature in our system is Saturn with its eight moons and grand system of rings. The first thought that was suggested by those rings, when their character first became known, was the nebular theory of planetary origin. And now that the spectroscope has demonstrated beyond doubt the absolute identity, in composition, of sun, planets and stars, this visible instance of the ring-condition of a planet furnishes a demonstration even more convincing than written history or laboratory experiments, of the abso-

late truth of the theory above set forth of the origin of suns and planets. The existence, in space, of comets, asteroids, meteors, etc., is easily accounted for on this theory, as merely fragmentary bodies of matter, observing the same laws of gravitation, rotation, etc., as the larger bodies.

"Thus" to quote the words of the little pamphlet before us, "The present state of the solar system is a living picture of the entire history of a single planet. From the solar fire-mountain to ring-girt Saturn—from Saturn to storm-battered Jupiter—from Jupiter to the sunny summer time of our own planet—from earth to autumn-browned Mars, and from Mars to the wintry silence and desolation of the dark gulches of the Moon—here is a series of stages which carry thought back into the eternity long lapsed, and onward into the measureless depths of the future, and confer upon human intelligence a sort of exemption from the limitations of finite existence."

This little pamphlet alluded to, which may be bought of Libby & Swett, No. 3 New Montgomery street, for 25 cents, presents a succinct statement by Prof. Winchell, of the University of Michigan, of the principle facts elicited by the combination of the telescope and spectroscopic in the study of the heavenly bodies, a mere reference to which we have made above. It forms No. 7 of a series of concise papers upon various scientific subjects, now in course of publication by Estes & Lauriat, of Boston, also for sale as above. These publications have thus far been prepared with special reference to the capacities and understanding of the general reader, and are presented in a most felicitous and attractive style. This growing demand for books of this character, devoted to popular sciences, in all its various phases, is one of the most encouraging signs of the times; and so long as the supply is continued, and kept free from matter which is too abstruse and technical to be clearly understood by the average reader, we believe the demand will not only continue but increase, until the great mass of the sensational reading of the day, as well as the more unprofitable light literature, with which the country is flooded, shall be so neglected as to be unremunerative to the publishers.

Narrow-Gauge Railroads.

The people of the Pacific Coast are fully alive to the importance of railroad communication, and strenuous efforts are being made in various localities to improve property and facilities of transportation by building roads. Narrow gauge lines are in great favor, as they are built at a comparatively small expense, and are peculiarly adapted for the generally mountainous character of the Pacific Slope. As will be seen by the following recent railroad news, considerable attention is being turned to the subject, and several lines are in process of construction.

Measurements are being taken to get the proposed narrow-gauge railroad from Oroville to Reno started. It is said that about \$250,000 has already been subscribed.

It is understood that the San Joaquin and Tulare Narrow Gauge Railroad Co. intend pushing their road through at once. The Engineer Corps were at work in Stockton on the 12th inst., prospecting for a starting point.

The ceremony of breaking ground on the Salt Lake, Sevier Valley and Pioche Railroad took place at Salt Lake on the 14th inst. It is expected that the line will be opened to Salt Lake by July 4th, and to Stockton by the latter part of the Summer.

The Wahsatch and Jordan Valley narrow gauge railroad is completed to Granite, at the mouth of Little Cottonwood Cañon, Utah. The total distance is twenty-one miles. This road will afford great facilities for transportation of ores from the rich and extensive mineral district in the Cañon. It is expected that the road will be completed to the Emma and Flagstaff mines by the 1st of June.

The work of grading for a branch narrow-gauge of the Utah Northern Railroad from Bingham City to Corinne, is going on rapidly.

In connection with the Elko and Hamilton (White Pine) narrow-gauge railroad, the Reese River Reveille says that Mr. A. A. Cohen a prominent railroad man of California, has deposited with him by Messrs. Gilmer and Sanbury the sum of \$150,000 in coin as a deposit on three ship-loads of railroad iron and rolling stock—sufficient to complete 50 miles of road.

The Saucelito Herald thinks that a through train from Saucelito to San Rafael on the narrow-gauge railroad will be running before four months are over. Some 800 men are now at work grading between White's Hill and Strawberry Point. At White's Hill a tunnel 1,200 feet long will be run, and a shorter one, two miles south of the large one will shortly be commenced.

The people of Santa Cruz county have recently held a meeting to take into consideration the propriety of building a narrow-gauge

railroad in that locality, and the following resolution, published in this Sentinel, was adopted:

Resolved, That the Executive Railroad Committee be instructed to immediately proceed with the organization of a railroad company, having for its object the construction of a narrow-gauge railroad from Watsonville, thence through the town of Santa Cruz and along or near the coast to the northern line of the county; and that canvassers be appointed to obtain subscriptions, so as to enable us to accept the county aid of \$5,000 per mile, on the terms agreed upon with our Board of Supervisors.

Improved Door and Gate Hinges.

Among the many convenient devices needed by the community has been an efficient door and gate hinge, which could be made cheaply and at the same time be durable and cause the door or gate to close automatically without the intervention of springs, weights or intricate mechanism. Many attempts have been made to fill the want but until recently most of the inventions have either been too complicated and bulky or too expensive to warrant a general introduction. The objections to former devices would seem to be overcome by Norton's door and gate hinge, a recent invention which is shown in the accompanying cuts. It will be perceived at a glance that there is no intricate mechanism in connection with this device. So there is no danger of its getting out of order.

There are two classes of this hinge, the single and double, both of which are shown. The single hinge is applicable to doors or common

There is no necessity of a latch, for the hinge will keep the gate in its proper position when closed. There is very little friction on the hinge, and no liability for it to get out of order. With a large gate a horseman can pass through either way, and it will close automatically behind him. When a team is to be driven through, by merely opening the gate a little wider it remains open, and a gentle twist will release it, when it will close itself. The gate is not thrown out of line by this device; it merely raises it straight up the height of the incline when it is opened. For "front gates" it is particularly adapted, since the gate will always close after any one passes through. Messrs Geo. B. Davis and H. H. Magill own the patent right of this invention for this coast, and Mr. Geo. B. Davis, of Alameda, Alameda county, Cal., has exclusive rights in the territory east of the Rocky Mountains. The hinges are cast in different sizes, and their neatness, durability and practical utility will no doubt cause them to be generally introduced. Mr. Davis is having a number of them manufactured in this city, and will shortly make arrangements for turning them out in large quantities.
